Introduction to the topic of this book

Poincaré sagte gelegentlich, dass alle Mathematik eine Gruppenge- schichte war. Ich erzählte ihm dann über dein Programm, das er nicht kannte.

Poincaré was saying that all of mathematics was a tale about groups. I then told him about your program, which he didn’t know about.

(Letter from Sophus Lie to Felix Klein, October 1882)

Since this book is called “Symmetry” it is reasonable to hope that by the time you’ve reached the end you’ll have a clear idea of what symmetry means.

Ideally the answer should give a solid foundation for dealing with questions about symmetries. It should also equip you with language with which to talk about symmetries, making precise – but also reflecting faithfully – the intuition humans seem to be born with.

So, we should start by talking about how one intuitively can approach the subject while giving hints about how this intuition can be made into the solid, workable tool, which is the topic of this book.

What is symmetry?

When we say that something is “symmetric” or possesses many “symmetries”, we mean that the thing remains unchanged, even if we “do things to it.” The best examples to begin with is if the something is some shape, for instance this square □. Rotating by 90 degrees doesn’t change it, so we may say that “rotation by 90 degrees is a symmetry of □.” Of course, rotating by 90 degrees will move individual points in □, but that is not of essence – the shape remains the same. However, the outcome of rotating by 360 degree or not at all is the same - even from the point of view of each individual point in □ – so it probably feels contrived to count rotations by 0 and 360 degrees as different rotations.

It feels reasonable to consider the rotations by 0°, 90°, 180°, and 270° to be all the (rotational) symmetries of □. Two thoughts may strike you:

(1) are these all the symmetries?

(2) “rotation” indicates a motion, through different squares, joining □ with itself via a “journey in the world of squares”.

The following cartoon animates a rotation of □ by 90°. The center of the square should be thought of as being in the same place all the time.
How is that reconcilable with a precise notion of symmetry?

The answer to the first question clearly depends on the context. For example, if we allow reflections the answer is “no”. Each context has its own answer to what the symmetries of the square are.

Actually, the two questions should be seen as connected. If a symmetry of □ is like a round trip (loop) in the world (type) of squares, what symmetries are allowed is dependent on how big a “world of squares” we consider. Is it, for instance, big enough to contain a loop representing a reflection?

We argue that in order to pin down the symmetries of a thing (a “shape”), all you need to do is specify

(1) a type $X$ (of things), and

(2) the particular thing $x$ (in $X$).

It is (almost) that simple!

Note that this presupposes that our setup is strong enough to support the notion of a round trip.

From “things” to mathematical objects

Different setups have different advantages. The theory of sets is an absolutely wonderful setup, but supporting the notion of a round trip in sets requires at the very least developing fields like *mathematical analysis*, *topology* and *homotopy theory*, which (while fun and worthwhile in itself) is something of a detour.

The setup we adopt, homotopy type theory, or univalent foundations, seems custom-built for supporting the notion of a round trip of a thing $x$ in a type $X$. We get support for important operations on round trips of $x$: one can do such round trips after another (composition), one can go any round trip in the reversed direction (inverse), and there is always the trivial round trip of staying in place (unit). This provides round trips with a structure that is called a *group* in mathematics, satisfying all the properties that these operations ought to have.

In practice, one of the most important things is to be able to *compare* symmetries of “thing 1” and “thing 2”. In our case this amounts to nothing but a function, $f : X_1 \to X_2$, that takes thing 1, $x_1$ in $X_1$, to thing 2, $x_2$ in $X_2$. 
While such comparisons of symmetries are traditionally handled by something called a group homomorphism which is a function satisfying a rather long list of axioms, in our setup the only thing we need to know of the function is that it really does take thing 1 to thing 2 – everything else then follows naturally.

Some important examples have provocatively simple representations in this framework. For instance, consider the circle shown in the margin, with one designated point $x$ on it. Since symmetries of $x$ are interpreted as loops, you see that you have a loop for every integer – the number 7 can be represented by looping seven times counterclockwise. As we shall see, in our setup any loop in the circle is naturally identified with a unique integer (the winding number if you will). Everything you can wish to know about the structure of the group of integers is built-in in the circle.

Another example is the free group of words in two letters $a$ and $b$. This is represented by the figure eight in the margin. In order to be able to distinguish the two circles we call them $a$ and $b$, with the point $x$ as the (only) point on both. The word $a b^2 a^{-1}$ is represented by looping around circles $a$ and $b$ respectively 1, 2 and $-1$ times in succession – notice that since the $b^2$ is in the middle it prevents the $a$ and the $a^{-1}$ from meeting and cancelling each other out. If you wanted the abelian group on the letters $a$ and $b$ (where $a$ and $b$ are allowed to move past each other), you should instead look at the torus:

Just why this last example works can remain a puzzle for now.

The importance of the ambient type $X$ “of things”

In many situations, the type $X$ “of things” can be more difficult to draw, or to define mathematically. For instance, what is the “type of all squares” which we discussed earlier, representing all rotational symmetries of $\Box$? You have perhaps already visualized it as the type of all squares in the plane, with $\Box$ being the shape the loop must start and stop in. This idea works well for the oriented square depicted in the margin. Note that the only reflective symmetry of the oriented square is reflection in the center – and the outcome is the same as a rotation by $180^\circ$. However, for $\Box$ we would get reflective symmetries that are not rotations. It is actually a little difficult to come up with a simple geometry of the plane that gives exactly the rotational symmetries of $\Box$. Later in the book, we will first pursue an algebraic approach, using that any rotational symmetry of $\Box$ can be reached by doing the $90^\circ$-rotation a few times, together with the fact that taking any loop four times reduces to not doing anything at all: they represent the cyclic group of order four.

A by-product of this line of thinking is the distinguished position of the circle. To express this it is convenient to give names to things: let
• be the chosen base point in the circle and \( \lor \) the loop winding once around the circle counterclockwise. Then a symmetry of a shape \( x_0 \) in \( X \) is uniquely given by the image of \( \lor \) under a function \( S^1 \to X \) taking \( \cdot \) to \( x_0 \). So,

the study of symmetries is the study of (pointed) functions between types of things, with the circle being the type that gives you access to individual symmetries.

This is similar to the idea of replacing membership in a set \( S \) by function from a one-point set 1 into \( S \): a point \( s \) in \( S \) is uniquely given by the function \( 1 \to S \) taking the value \( s \).

Just as you don’t need much information about the one-point set to get this to work, you don’t need much information about the circle to embark on a study of symmetries. Essentially you need to know of \( \cdot \) and \( \lor \), and that there is no “hidden relation” between the symmetries of \( \cdot \). Contrast this to the type of squares which has such a “hidden relation”: where we identified a 360° rotation with doing nothing. This point of view has the benefit of being readily formalized while offering geometric intuition.

Symmetries have natural scopes

The natural scope of the symmetries of a thing \( x \) in a type \( X \) are the things in \( X \) that can be reached from \( x \) by a journey in \( X \).

Let’s make this precise with an example. In our setup, as a consequence of univalence, journeys from one set to another in the type of sets are uniquely given by one-to-one correspondences between these sets, commonly called bijections.

Now consider the set \( \{1, 2, 3\} \). Then a symmetry of \( \{1, 2, 3\} \) in the type of not needed: finite sets amounts to the same thing as a symmetry of \( \{1, 2, 3\} \) in the type of sets with three elements: a symmetry of \( \{1, 2, 3\} \) will not “pass through” sets that have, say, five elements. Think of the type of finite sets as being the disjoint union of all the types of sets with \( n \)-elements, where \( n = 0, 1, 2, \ldots \) : if a symmetry is a loop it should not be allowed to jump between the type of sets with three elements and the type of sets with five elements.

In fact, any type \( X \) can be naturally divided into “components”: each element \( x_0 \) in \( X \) belongs to one and only one component and the one \( x_0 \) belongs to we call \( X_{x_0} \), and the symmetries of \( x_0 \) in \( X \) may be identified with the symmetries of \( x_0 \) in \( X_{x_0} \). Hence from the perspective of symmetries of \( x_0 \) only the component containing it matters, and we confine our discussion to “connected” types of things, i.e., those having just one component.

The geometric intuition also points to the possibility of seemingly different symmetries being identified: when looping once around the circle it shouldn’t matter “how” or “how fast” you do it. In the picture of the abelian group on two letters \( a \) and \( b \) [here a picture of a torus with a base point \( x_0 \) and the two standard generators \( a \) and \( b \) (in color), together with a more frivolous loop (in pink) homotopic to \( a \)] you might think of a symmetries of \( x_0 \) as a rubber band confined to the circle and pinned to \( x_0 \). In the picture we’ve drawn such a rubber band which will
contract to \( a \), and this contraction we consider as an **identification of the two symmetries**. In the language we adopt, this is hard-wired, and so our arguments are independent of any picture: pictures serve only as inspirations and are very helpful when trying to discover proofs.

Our use of univalent foundations has several advantages. Roughly, univalence is the assertion that two types are “equivalent” if and only if there is a “path” (called an “identification”) between them in the (large) “type of types”. In group theory, two groups share exactly the same properties if there is an “isomorphism” between them (an invertible homomorphism), and with univalent foundation this is manifested by the isomorphism corresponding to a path between the groups in the type of groups. Hence we can use this path to transport any theorem about one group to the other: the two groups are “identified”. The power of univalence is hard to overstate; it will simplify many proofs and make many statements accessible that otherwise would have been out of reach.

There are many kinds of symmetry and many ways of studying it. Euclidean plane geometry is the study of properties that are invariant under rigid motions of the plane. Other kinds of geometry arise by considering other notions of transformation. Univalent mathematics gives a new perspective on symmetries: Motions of the plane are forms of identifying the plane with itself in possibly non-trivial ways. It may also be useful to consider different presentations of planes (for instance as embedded in a common three-dimensional space) and different identifications between them. For instance, when drawing images in perspective we identify planes in the scene with the image plane, not in a rigid Euclidean way, but rather via a perspectivity (see Fig. ?). This gives rise to projective geometry.

Does that mean that a plane from the point of view of Euclidean geometry is not the same as a plane from the point of view of projective or affine geometry? Yes. These are of different types, because they have different notions of identification, and thus they have different properties.

Here we follow Quine’s dictum: No entity without identity! To know a type of objects is to know what it means to identify representatives of the type. The collection of self-identifications (self-transformations) of a given object form a group.

Group theory emerged from many different directions in the latter half of the 19th century. Lagrange initiated the study of the invariants under permutations of the roots of a polynomial equation \( f(x) = 0 \), which culminated in the celebrated work of Abel and Galois. In number theory, Gauss had made detailed studies of modular arithmetic, proving for instance that the group of units of \( \mathbb{Z}/n\mathbb{Z} \) is cyclic for \( n = \ldots, \). Klein was bringing order to geometry by considering groups of transformation, while Lie was applying group theory in analysis to the study of differential equations.

Galois was the first to use the word “group” in a technical sense, speaking of collections of permutations closed under composition. He realized that the existence of resolvent equation is equivalent to the existence of a normal subgroup of prime index in the group of the equation.

There’s a subtle point – which we probably should stay quiet about in an introduction, but which may be a source of confusion if brushed under the carpet – that a priori there could have been “several ways” in which two symmetries should be identified. For many purposes this poses no problem, but we want to present a theory that mirrors the classical theory faithfully, and so restrict our “types of things” where there aren’t multiple ways of identifying symmetries [the technical term - when we get that far will be “pointed connected groupoids”]. This means that types like the sphere [picture of a sphere with \( \pi_0 \) on the red equator] are disallowed: there are fundamentally different ways of identifying the symmetry represented of \( \pi_0 \) by the equator with the trivial symmetry: when thought of as a rubber band the equator can contract either over the North or the South poles (or more complicated ways). There’s something called “truncation” which can fix any type to one of the desired sort where identifications of symmetries are unique.
REMEMBER: a section on planar tessellations [need help here]

1.0.1 Who is this book for?
At the outset the plan for this book was that it ought to cater for two very
groups of readers. If you already have a classical first course in abstract
group theory, this text has as its ambition that you should gain a new
perspective on the material, and at the same time learn about homotopy
type theory by seeing it applied to a field you are familiar with. However,
at the outset, another audience seemed just as plausible to us: what if
you’re not well versed in abstract algebra, but open to learning about it
from a type theoretic perspective? This might apply to a computer science
student with aspirations towards the many applications of algebra.
The first audience may have become our predominant target as the
book has progressed, partially because it probably is more sizable than
the second since most students have been brain-washed to think only in
terms of sets at the time they’re ready for this book.

1.0.2 Outline of the book
OLD
This book is about symmetry and its many manifestations in mathe-
matics.

Groupoids vs groups. The type of all squares in a euclidean plane
form a groupoid. It is connected, because between any two there exist
identifications between them. But there is no canonical identification.
When we say “the symmetry group of the square”, we can mean two
things: 1) the symmetry group of a particular square; this is indeed a
group, or 2) the connected groupoid of all squares; this is a “group up
to conjugation”.

Vector spaces. Constructions and fields. Descartes and cartesian
gometry.
Klein’s EP:

Given a manifold and a transformation group acting on it, to
investigate those properties of figures on that manifold that
are invariant under transformations of that group.

and

Given a manifold, and a transformation group acting on it,
to study its invariants.

Invariant theory had previously been introduced in algebra and studied
by Clebsch and Gordan.
(Mention continuity, differentiability, analyticity and Hilbert’s 5th
problem?)

Any finite automorphism group of the Riemann sphere is conjugate
to a rotation group (automorphism group of the Euclidean sphere).
[Dependency: diagonalizability] (Any complex representation of a finite
group is conjugate to a unitary representation.)

All of mathematics is a tale, not about groups, but about $\infty$-groupoids.
However, a lot of the action happens already with groups.
Glossary of coercions

Throughout this book we will use the following coercions to make the text more readable.

- If $X$ is the pointed type $(A, a)$, then $x : X$ means $x : A$.
- On hold, lacking context: If $p$ and $q$ are paths, then $(p, q)$ means $(p, q)^\equiv$.
- If $e$ is a pair of a function and a proof, we also use $e$ for the function.
- If $e$ is an equivalence between types $A$ and $B$, we use $\bar{e}$ for the identification of $A$ and $B$ induced by univalence.
- If $p : A = B$ with $A$ and $B$ types, then we use $\tilde{p}$ for the canonical equivalence from $A$ to $B$ (also only as function).
- If $X$ is $(A, a, \ldots)$ with $a : A$, then $\text{pt}_X$ and even just pt mean $a$.

How to read this book

A word of warning. We include a lot of figures to make it easier to follow the material. But like all mathematical writing, you’ll get the most out of it, if you maintain a skeptical attitude: Do the pictures really accurately represent the formal constructions? Don’t just believe us: Think about it!

The same goes for the proofs: When we say that something clearly follows, it should be clear to you. So clear, in fact, that you could go and convince a proof assistant, should you so desire.

An introduction to univalent mathematics

2.1 What is a type?

In some computer programming languages, all variables are introduced along with a declaration of the type of thing they will refer to. Knowing the type of thing a variable refers to allows the computer to determine which expressions in the language are grammatically well formed\(^1\), and hence valid. For example, if \( s \) is a string\(^2\) and \( x \) is a real number, we may write \( 1/x \), but we may not write \( 1/s \).

To enable the programmer to express such declarations, names are introduced to refer to the various types of things. For example, the name \( \text{Bool} \) may be used to declare that a variable is a Boolean value\(^4\), \( \text{Int} \) may refer to 32-bit integers, and \( \text{Real} \) may refer to 64-bit floating point numbers\(^5\).

Types occur in mathematics, too, and are used in the same way: all variables are introduced along with a declaration of the type of thing they will refer to. For example, one may say “consider a real number \( x \)”, “consider a natural number \( n \)”, “consider a point \( P \) of the plane”, or “consider a line \( L \) of the plane”. After that introduction, one may say that the type of \( n \) is natural number and that the type of \( P \) is point of the plane. Just as in a computer program, type declarations such as those are used to determine which mathematical statements are grammatically well formed. Thus one may write “\( P \) lies on \( L \)” or \( 1/x \), but not “\( L \) lies on \( P \)” nor \( 1/L \).

Often ordinary English writing is good enough for such declarations in mathematics expositions, but, for convenience, mathematicians usually introduce symbolic names to refer to the various types of things under discussion. For example, the name \( \mathbb{N} \) is usually used when declaring that a variable is a natural number, the name \( \mathbb{Z} \) is usually used when declaring that a variable is an integer, and the name \( \mathbb{R} \) is usually used when declaring that a variable is a real number. Ways are also given for constructing new type names from old ones: for example, the name \( \mathbb{R} \times \mathbb{R} \) may be used when declaring that a variable is a point of the plane, for it conveys the information that a point of the plane is a pair of real numbers.

Once one becomes accustomed to the use of names such as \( \mathbb{N} \) in mathematical writing and speaking, it is natural to take the next step and regard those names as denoting things that exist. Thus, we shall refer to \( \mathbb{N} \) as the type of all natural numbers, and we will think of it as a mathematical object in its own right. Intuitively and informally, it is a collection whose members (or elements) are the natural numbers.

\(^1\)The grammar of a programming language consists of all the language’s rules. A statement or expression in a programming language is grammatically well formed if it follows all the rules.

\(^2\)A string is a sequence of characters, such as “qwertyuiop”.

\(^3\)In a programming language, the well formed expression \( 1/x \) may produce a run-time error if \( x \) happens to have the value 0.

\(^4\)A Boolean value is either \texttt{true} or \texttt{false}.

\(^5\)An example of a floating point number is \( 625 \times 2^{33} \) – the mantissa \( 625 \) and the exponent 33 are stored inside the floating point number. The “point”, when the number is written in base 2 notation, is called “floating”, because its position is easily changed by modifying the exponent.

\(^6\)In mathematics there are no “run-time” errors; rather, it is legitimate to write the expression \( 1/x \) only if we already know that \( x \) is a non-zero real number.
Once we view the various types as existing as mathematical objects, they become worthy of study. The language of mathematics is thereby improved, and the scope of mathematics is broadened. For example, we can consider statements such as “\( \mathbb{N} \) is infinite” and to try to prove it.

Historically, there was some hesitation about introducing the collection of all natural numbers as a mathematical object, perhaps because if one were to attempt to build the collection from nothing by adding numbers to it one at a time, it would take an eternity to complete the assembly. We won’t regard that as an obstacle.

We have said that the types of things are used to determine whether mathematical statements are well formed. Therefore, if we expect “\( \mathbb{N} \) is infinite” to be a well-formed statement, we’ll have to know what type of thing \( \mathbb{N} \) is, and we’ll have to have a name for that type. Similarly, we’ll have to know what type of thing that type is, and we’ll have to have a name for it, and so on forever. Indeed, all of that is part of what will be presented in this chapter.

### 2.2 Types, elements, families, and functions

In this section we build on the intuition imparted in the previous section.

In univalent mathematics,\(^8\) types are used to classify all mathematical objects. Every mathematical object is an element (or a member) of some type. Before one can talk about an object of a certain type, one must introduce the type itself. There are enough ways to form new types from old ones to provide everything we need to write mathematics.

One expresses the declaration that an object \( a \) is an element of the type \( X \) by writing \( a : X \).

Using that notation, each variable \( x \) is introduced along with a declaration of the form \( x : X \), which declares that \( x \) will refer to something of type \( X \), but provides no other information about \( x \). The declared types of the variables are used to determine which statements of the theory are grammatically well formed.

After introducing a variable \( x : X \), it may be possible to form an expression \( T \) representing a type, all of whose components have already been given a meaning. (Here the variable \( x \) is regarded also as having already been given a meaning, even though the only thing known about it is its type.) To clarify the dependence of \( T \) on \( x \) primarily, we may write \( T(x) \) (or \( T_x \)) instead of \( T \). Such an expression will be called a family of types parametrized by the variable \( x \) of type \( X \). Such a family provides a variety of types, for, if \( a \) is any expression denoting an object of \( X \), one may replace all occurrences of \( x \) by \( a \) in \( T \), thereby obtaining a new expression representing a type, which may be regarded as a member and which may be denoted by \( T(a) \).

Naturally, if the expression \( T \) doesn’t actually involve the variable \( x \), then the members of the family are all the same, and we’ll refer to the family as a constant family of types.

Here’s an example of a family of types: let \( T \) be the type of all natural numbers greater than 2. For any element \( n \) of \( T \) we let \( P_n \) be the type of \( n \)-sided polygons in the plane. It gives a family of types parametrized by the elements of \( T \).\(^9\) One of the members of the family is the type \( P_5 \) of all pentagons in the plane.

\(^7\)TO DO: Include some pointers to discussions of potential infinity and actual infinity, perhaps.

\(^8\)The term “univalent” is a word coined by Vladimir Voevodsky, who introduced it to describe his principle that types that are equivalent in a certain sense can be identified with each other. The principle is stated precisely in Principle 2.13.2. As Voevodsky explained, the word comes from a Russian translation of a mathematics book, where the English mathematical term “faithful” was translated into Russian as the Russian word that sounds like “univalent”. He also said “Indeed these foundations seem to be faithful to the way in which I think about mathematical objects in my head.”

\(^9\)The notation in mathematics based on set theory that corresponds (sort of) to this is \( a \in X \).

\(^{10}\)See if you like my solution. If so, remove footnote.
A family of types may be parametrized by more than one variable. For example, after introducing a variable \( x : X \) and a family of types \( T \) parametrized by \( x \), we may introduce a variable \( t : T \). Then it may be possible to form an expression \( S \) representing a type that involves the variables \( x \) and \( t \). Such an expression will be called a family of types parametrized by \( x \) and \( t \), and we may write \( S(x, t) \) instead of \( S \) to emphasize the dependence on \( x \) and \( t \). The same sort of thing works with more variables.

After introducing a variable \( x : X \) and a family of types \( T \), it may be possible to form an expression \( e \) of type \( T \), all of whose components have already been given a meaning. Such an expression will also be called a family of elements of \( T \) parametrized by the elements of \( X \), when we wish to focus on the dependence of \( e \) (and perhaps \( T \)) on the variable \( x \). To clarify the dependence of \( e \) on \( x \) primarily, we may write \( e(x) \) (or \( e_a \)) instead of \( e \). Such a family provides a variety of elements of members of the family \( T \), for, if \( a \) is any expression denoting an object of \( X \), one may replace all occurrences of \( x \) by \( a \) in \( e \) and in \( T \), thereby obtaining an element of \( T(a) \), which may be regarded as a member of the family \( e \) and which will be denoted by \( e(a) \).

Naturally, if the expressions \( e \) and \( T \) don't actually involve the variable \( x \), then the members of the family are all the same, and we'll refer to the family as a constant family of elements.

Here's an example of a family of elements in a constant family of types: we let \( n \) be a natural number and consider the real number \( \sqrt{n} \). It gives a family of real numbers parametrized by the natural numbers. (The family may also be called a sequence of real numbers). One of the members of the family is \( \sqrt{\Pi} \).

Here's an example of a family of elements in a (non-constant) family of types. As above, let \( T \) be the type of all natural numbers greater than 2 and let \( P_n \) be the type of \( n \)-sided polygons in the plane, for any \( n : T \). Now consider the regular \( n \)-sided polygon \( p_n \) of radius 1 with a vertex on the positive \( x \)-axis, for any \( n : T \). We see that \( p_n : P_n \). One of the members of this family of elements \( p_n \) is the regular pentagon \( p_5 \) of radius 1 with a vertex on the positive \( x \)-axis. The pentagon \( p_5 \) is an element of the type \( P_5 \), which is a member of the family of types \( P_n \ (n : T) \). In short, \( 5 : T \) and \( p_5 : P_5 \).

The type \( X \) containing the variable for a family of types or a family of elements is called the parameter type of the family.

Just as a family of types may depend on more than one variable, a family of elements may also depend on more than one variable.

Families of elements can be enclosed in mathematical objects called functions (or maps), as one might expect. Let \( e \) be a family of elements of a family of types \( T \), both of which are parametrized by the elements \( x \) of \( X \). We use the notation \( x : X \mapsto e \) for the function that sends an element \( a \) of \( X \) to the element \( e(a) \) of \( T(a) \); the notation \( x : X \mapsto e \) can be read as "\( x \) maps to \( e \)" or "\( x \) goes to \( e \)". (Recall that \( e(a) \) is the expression that is obtained from \( e \) by replacing all occurrences of \( x \) in \( e \) by \( a \).) If we name the function \( f \), then that element of \( T \) will be denoted by \( f(a) \). The type of the function \( x : X \mapsto e \) is called a product type and will be denoted by \( \prod_{x : X} T(x) \). If \( T \) is a constant family of types, then the type will also be called a function type and will be denoted by \( X \to T \). Thus when we
write \( f : X \to T \), we mean that \( f \) is an element of the type \( X \to T \), and we are saying that \( f \) is a function from \( X \) to \( T \). The type \( X \) may be called the domain of \( f \), and the type \( T \) may be called the codomain of \( f \).

An example of a function is the function \( n \mapsto \sqrt{n} \) of type \( \mathbb{N} \to \mathbb{R} \).

Another example of a function is the function \( n \mapsto p_n \) of type \( \prod_{n : \mathbb{N}} P_n \), where \( P_n \) is the type of polygons introduced above, and \( p_n \) is the polygon introduced above.

Another example of a function is the function \( m \mapsto (n \mapsto m + n) \) of type \( \mathbb{N} \to (\mathbb{N} \to \mathbb{N}) \). It is a function that accepts a natural number as argument and returns a function as its value. The function returned is of type \( \mathbb{N} \to \mathbb{N} \). It accepts a natural number as argument and returns a natural number as value.

The reader may wonder why the word “product” is used when speaking of product types. To motivate that, we consider a simple example informally. We take \( T \) to be a type with just two elements, \( b \) and \( c \). We take \( T(x) \) to be a family of types parametrized by the elements of \( X \), with \( T(b) \) being a type with \( 5 \) elements and \( T(c) \) being a type with \( 11 \) elements. Then the various functions \( f \) of type \( \prod_{x : X} T(x) \) are plausibly obtained by picking a suitable element for \( f(b) \) from the \( 5 \) possibilities in \( T(b) \) and by picking a suitable element for \( f(c) \) from the \( 11 \) possibilities in \( T(c) \). The number of ways to make both choices is \( 5 \times 11 \), which is a product of two numbers. Thus \( \prod_{x : X} T(x) \) is sort of like the product of \( T(b) \) and \( T(c) \), at least as far as counting is concerned.

The reader may wonder why we bother with functions at all: doesn’t the expression \( e \) serve just as well as the function \( x \mapsto e \), for all practical purposes? The answer is no. One reason is that the expression \( e \) doesn’t inform the reader that the variable under consideration is \( x \). Another reason is that we may want to use the variable \( x \) for elements of a different type later on: then \( e(x) \) is no longer well formed. For example, imagine first writing this: “For a natural number \( n \) we consider the real number \( \sqrt{n} \)” and then writing this: “Now consider a triangle \( n \) in the plane.” The result is that \( \sqrt{n} \) is no longer usable, whereas the function \( n \mapsto \sqrt{n} \) has enclosed the variable and the family into a single object and remains usable.\(^{11}\)

Once a family \( e \) has been enclosed in the function \( x \mapsto e \), the variable \( x \) is referred to as a dummy variable or as a bound variable.\(^{12}\) This signifies that the name of the variable no longer matters, in other words, that \( x \mapsto e(x) \) and \( t \mapsto e(t) \) may regarded as identical. Moreover, the variable \( x \) that occurs inside the function \( x \mapsto e \) is regarded as unrelated to variables \( x \) which may appear elsewhere in the discussion.

If the variable \( x \) in our notation \( x \mapsto e(x) \) is a dummy variable, and its name doesn’t matter, then we may consider the possibility of not specifying a variable at all. We introduce now a methodical way to do that, by replacing the occurrences of the variable \( x \) in the expression \( e(x) \) by an underscore, yielding \( e(_) \) as alternative notation for the function \( x \mapsto e(x) \). For example, the notation \( \sqrt{\_} \) can serve as alternative notation for the function \( n \mapsto \sqrt{n} \) introduced above, and \( 2 + \_ \) can serve as alternative notation for the function \( n \mapsto 2 + n \) of type \( \mathbb{N} \to \mathbb{N} \).

We have mentioned above the possibility of giving a name to a function. We expand on that now by introducing notation for making and for using definitions.

\(^{11}\)Students of trigonometry are already familiar with the concept of function, as something enclosed this way. The sine and cosine functions, \( \sin \) and \( \cos \), are examples.

\(^{12}\)Students of calculus are familiar with the concept of dummy variable and are accustomed to using identities such as \( \int_a^b f(t) \, dt = \int_a^b f(x) \, dx \).
The notation \( x \equiv z \) will be an announcement that we are defining the expression \( x \) to be the expression \( z \), all of whose components have already been given a meaning; in that case, we will say that \( x \) has been defined to be (or to mean) \( z \). The forms allowed for the expression \( x \) will be made clear by the examples we give.

For example, after writing \( n \equiv 12 \), we will say that \( n \) has been defined to be 12.

For another example, naming the function \( x \mapsto e(x) \) as \( f \) (as we did above) can be done by writing \( f \equiv (x \mapsto e(x)) \). Alternatively and more traditionally, we may write \( f(x) \equiv e(x) \). Both mean that \( f \) has been defined to be \( x \mapsto e(x) \) and that, consequently, \( f(a) \) has been defined to be \( e(a) \), for any element \( a \) of \( X \).

The notation \( b \equiv c \) will denote the statement that the expressions \( b \) and \( c \) become the same thing if all the subexpressions within \( b \) or \( c \) are expanded according to their definitions, if any; in that case, we will say that \( b \) and \( c \) are the same by definition. For example, after writing \( n \equiv 12 \) and \( m \equiv n \), we may say that \( j + 12 \equiv j + m \) and that \( m \times 11 \equiv 12 \times 11 \).

Whenever two expressions are the same by definition, we may replace one with the other inside any other expression, because the expansion of definitions is regarded as trivial and transparent.

We proceed now to the promised example. Consider functions \( f : X \to Y \) and \( g : Y \to Z \). We define the composite function \( g \circ f : X \to Z \) by setting \( g \circ f \equiv (a \mapsto g(f(a))) \). In other words, it is the function that sends an arbitrary element \( a \) of \( X \) to \( g(f(a)) \) in \( Z \). (The expression \( g \circ f \) may be read as “\( g \) circle \( f \)” or as “\( g \) composed with \( f \)”.) The composite function \( g \circ f \) may also be denoted simply by \( gf \).

Now consider functions \( f : X \to Y \), \( g : Y \to Z \), and \( h : Z \to W \). Then \( (h \circ g) \circ f \) and \( h \circ (g \circ f) \) are the same by definition, since applying the definitions within expands both expressions to \( a \mapsto h(g(f(a))) \). In other words, we have established that \( (h \circ g) \circ f \equiv h \circ (g \circ f) \). Thus, we may write \( h \circ g \circ f \) for either expression, without danger of confusion.

One may define the identity function \( \text{id}_X : X \to X \) by setting \( \text{id}_X \equiv (a \mapsto a) \). Application of definitions shows that \( f \circ \text{id}_X \) is the same by definition as \( a \mapsto f(a) \), which, by a standard convention, which we adopt\(^\dagger\), is to be regarded as the same as \( f \). In other words, we have established that \( f \circ \text{id}_X \equiv f \). A similar computation applies to \( \text{id}_Y \circ f \).

\(^\dagger\)The convention that \( f \equiv (a \mapsto f(a)) \) is referred to as the \( \eta \)-rule in the jargon of type theory.

In the following sections we will present various other elementary types and elementary ways to make new types from old ones.

### 2.3 Universes

In Section 2.2 we have introduced the objects known as types. They have elements, and the type an element belongs to determines the type of thing that it is. At various points in the sequel, it will be convenient for types also to be elements, for that will allow us, for example, to enclose families of types in functions. To achieve this convenience, we introduce types that are universes. Some care is required, for the first temptation is to posit a single new type \( U \) called the universe, so that every type is realized as an element of \( U \). This universe would be “the type of all types”, but introducing it would lead to an absurdity, for roughly the same reason that introduction of a “set of all sets” leads to the absurdity in traditional
mathematics known as Russell’s paradox.\footnote{In fact, type theory can trace its origins to Russell’s paradox, announced in a 1902 letter to Frege as follows: There is just one point where I have encountered a difficulty. You state that a function too, can act as the indeterminate element. This I formerly believed, but now this view seems doubtful to me because of the following contradiction. Let \( w \) be the predicate to be a predicate that cannot be predicated of itself. Can \( w \) be predicated of itself? From each answer its opposite follows. Therefore we must conclude that \( w \) is not a predicate. Likewise there is no class (as a totality) of those classes which, each taken as a totality, do not belong to themselves. To which Frege replied: Incidentally, it seems to me that the expression “a predicate is predicated of itself” is not exact. A predicate is as a rule a first-level function, and this function requires an object as argument and cannot have itself as argument (subject). Russell then quickly added Appendix B to his Principles of Mathematics (1903), in which he said that “it is the distinction of logical types that is the key to the whole mystery”, where types are the ranges of significance of variables. For more on the history of type theory, see Coquand\ref{footnote:coquand}.

\footnote{Thierry Coquand. “Type Theory”. In: The Stanford Encyclopedia of Philosophy. Ed. by Edward N. Zalta. Metaphysics Research Lab, Stanford University, 2018. url: https://plato.stanford.edu/archives/fall2018/entries/type-theory/}} Some later approaches to set theory included the notion of a class, with the collection of all sets being the primary example of a class. Classes are much like sets, and every set is a class, but not every class is a set. Then one may wonder what sort of thing the collection of all classes would be. Such musings are resolved in univalent mathematics as follows.

(1) There are some types called universes.

(2) If \( \mathcal{U} \) is a universe, and \( X : \mathcal{U} \) is an element of \( \mathcal{U} \), then \( X \) is a type.

(3) If \( X \) is a type, then it appears as an element in some universe \( \mathcal{U} \). Moreover, if \( X \) and \( Y \) are types, then there is a universe \( \mathcal{U} \) containing both of them.

(4) If \( \mathcal{U} \) and \( \mathcal{U}' \) are universes, \( \mathcal{U} : \mathcal{U}' \), \( X \) is a type, and \( X : \mathcal{U} \), then also \( X : \mathcal{U}' \). (Thus we may regard \( \mathcal{U}' \) as being larger than \( \mathcal{U} \).)

(5) There is a particular universe \( \mathcal{U}_0 \), which we single out to serve as a repository for certain basic types to be introduced in the sequel. Moreover, \( \mathcal{U}_0 : \mathcal{U} \) for every other universe \( \mathcal{U} \), and thus \( \mathcal{U}_0 \) is the smallest universe.

It follows from the properties above that there are an infinite number of universes, for each one is an element of a larger one.

Now suppose we have a type \( X \) and a family \( T(x) \) of types parametrized by a variable \( x \) of type \( X \). Choose a universe \( \mathcal{U} \) with \( T(x) : \mathcal{U} \). Then we can make a function of type \( X \to \mathcal{U} \), namely \( f := (x \mapsto T(x)) \). Conversely, if \( f' \) is a function of type \( X \to \mathcal{U} \), then we can make a family of types parametrized by \( x \), namely \( T' := f'(x) \). The flexibility offered by this correspondence between families of types in \( \mathcal{U} \) and functions to \( \mathcal{U} \) will often be used.

\section{The type of natural numbers}

Here are Peano’s rules\footnote{Giuseppe Peano. Arithmetices principia: nova methodo. See also https://github.com/mdmahas/Peano_Book/ for a parallel translation by Vincent Verheyen. Fratres Bocca, t889. url: https://books.google.com/books?id=28GAAAAAAYAAJ.} for constructing the natural numbers in the form that is used in type theory.

(P1) there is a type called \( \mathbb{N} \) in the universe \( \mathcal{U}_0 \) (whose elements will be called natural numbers);

(P2) there is an element of \( \mathbb{N} \) called \( 0 \), called zero;

(P3) if \( m \) is a natural number, then there is also a natural number \( \text{succ}(m) \), called the successor of \( m \);

(P4) suppose we are given:

\begin{itemize}
  \item[a)] a family of types \( X(m) \) parametrized by a variable \( m \) of type \( \mathbb{N} \);
  \item[b)] an element \( a \) of \( X(0) \); and
  \item[c)] a family of functions \( g_m : X(m) \to X(\text{succ}(m)) \).
\end{itemize}

Then from those data we are provided with a family of elements \( f(m) : X(m) \), satisfying \( f(0) \equiv a \) and \( f(\text{succ}(m)) \equiv g_m(f(m)) \).
The first three rules present few problems for the reader. They provide us with the smallest natural number 0 : ℕ, and we may introduce as many others as we like with the following definitions.

1 \equiv \text{succ}(0)
2 \equiv \text{succ}(1)
3 \equiv \text{succ}(2)

\vdots

You may recognize rule (P4) as “the principle of mathematical induction”. We will refer to it simply as “induction on ℕ”. You may also recognize the function f in (P4) as “defined by recursion”.

The point of the induction principle is that the type \( X(m) \) of \( f(m) \) may depend on \( m \). An important special case is when \( X(m) \) does not depend on \( m \), that is, when \( X(m) \equiv Y \) for some type \( Y \). In this non-dependent case we refer to the principle as “the recursion principle for ℕ”. In other words, throughout this book, the difference between an induction principle and the corresponding recursion principle is that in the latter principle the type family is constant.

The resulting family \( f \) may be regarded as having been defined inductively by the two declarations \( f(0) \equiv a \) and \( f(\text{succ}(m)) \equiv g_m(f(m)) \), and indeed, we will often simply write such a pair of declarations as a shorthand way of applying rule (P4). The two declarations cover the two ways of introducing elements of \( \mathbb{N} \) via the use of the two rules (P2) and (P3). (In terms of computer programming, those two declarations amount to the code for a recursive subroutine that can handle any incoming natural number.)

With that notation in hand, speaking informally, we may regard (P4) above as defining the family \( f \) by the following infinite sequence of definitions.

\[
\begin{align*}
f(0) & \equiv a \\
f(1) & \equiv g_0(a) \\
f(2) & \equiv g_1(g_0(a)) \\
f(3) & \equiv g_2(g_1(g_0(a))) \\
\vdots
\end{align*}
\]

(The need for the rule (P4) arises from our inability to write down an infinite sequence of definitions in a finite amount of space, and from the need for \( f(m) \) to be defined when \( m \) is a variable of type \( \mathbb{N} \), and thus is not known to be equal to 0, nor to 1, nor to 2, etc.)

We may use induction on \( \mathbb{N} \) to define of iteration of functions. Let \( Y \) be a type, and suppose we have a function \( e : Y \to Y \). We define by induction on \( \mathbb{N} \) the \( m \)-fold iteration \( e^m : Y \to Y \) by setting \( e^0 \equiv \text{id}_Y \) and \( e^{\text{succ}(m)} \equiv e \circ e^m \). (Here we apply rule (P4) with the the type \( Y \to Y \) as the family of types \( X(m) \), the identity function \( \text{id}_Y \) for \( a \), and the function \( d \mapsto e \circ d \) for the family \( g_m : (Y \to Y) \to (Y \to Y) \) of functions.)

We may now define addition of natural numbers by induction on \( \mathbb{N} \). For natural numbers \( n \) and \( m \) we define \( n + m : \mathbb{N} \) by induction on \( \mathbb{N} \) with respect to the variable \( m \) by setting \( n + 0 \equiv n \) and \( n + \text{succ}(m) \equiv n \).
succ(n + m). (The reader should be able to extract the family \( X(m) \), the element \( a \), and the family of functions \( g_m \) from that pair of definitions.) Application of definitions shows, for example, that \( 2 + 2 \) and \( 4 \) are the same by definition, and thus we may write \( 2 + 2 \equiv 4 \), because both expressions reduce to \( \text{succ(succ(succ(0))))} \).

Similarly we define the product \( mn : \mathbb{N} \) by induction on \( m \) by setting \( 0 \cdot n \equiv 0 \) and \( \text{succ}(m) \cdot n \equiv (m \cdot n) + n \).

Alternatively (and equivalently) we may use iteration of functions to define addition and multiplication, by setting \( n + m \equiv \text{succ}^m(n) \) and \( m \cdot n \equiv (i \mapsto i + n)^m(0) \).

Finally, we may define the factorial function \( \text{fact} : \mathbb{N} \to \mathbb{N} \) by induction on \( \mathbb{N} \), setting \( \text{fact}(0) \equiv 1 \) and \( \text{fact}(\text{succ}(m)) \equiv \text{succ}(m) \cdot \text{fact}(m) \). (One can see that this definition applies rule (P4) with \( X(m) \equiv \mathbb{N} \), with 1 for \( a \), and with the function \( n \mapsto \text{succ}(m) \cdot n \) for \( g_m \).) Application of the definitions shows, for example, that \( \text{fact}(3) \equiv 6 \), as the reader may verify.

### 2.5 Identity types

One of the most important types is the identity type, which implements a notion of equality. Identity types are formed of a type and two elements of that type; we shall have no need to compare elements of different types.

Here are the rules for constructing and using identity types.

(E1) for any type \( X \) and for any elements \( a \) and \( b \) of it, there is an identity type \( a \rightsquigarrow b \); moreover, if \( X \) is an element of a universe \( \mathcal{U} \), then so is \( a \rightsquigarrow b \).

(E2) for any type \( X \) and for any element \( a \) of it, there is an element \( \text{refl}_a \) of type \( a \rightsquigarrow a \) (the name \( \text{refl} \) comes from the word “reflexivity”)

(E3) suppose we are given:

a) a type \( X \) and an element \( a : X \);

b) a family of types \( P(b, e, \ldots) \) parametrized by a variable \( b \) of type \( X \), a variable \( e \) of type \( a \rightsquigarrow b \), and perhaps some further variables; and

c) an element \( p \) of \( P(a, \text{refl}_a, \ldots) \).

Then from those data we are provided with a family of elements \( f(b, e, \ldots) : P(b, e, \ldots) \). Moreover, \( f(a, \text{refl}_a, \ldots) \equiv p \).

We will refer to an element \( i \) of \( a \rightsquigarrow b \) as an identification of \( a \) with \( b \). Since the word “identification” is a long one, we may also refer to \( i \) as a path from \( a \) to \( b \) – this has the advantage of incorporating the intuition that an identification may proceed gradually through intermediate steps.

The need to record, using the element \( i \), the way we identify \( a \) with \( b \) may come as a surprise, since normally, in mathematics, one is accustomed to regarding \( a \) as either equal to \( b \) or not. However, this reflects a situation commonly encountered in geometry when congruence of geometric figures is considered. For example, in Euclidean space, two equilateral triangles of the same size are congruent in six (different) ways. The chief novelty of univalent mathematics is that the basic
logical notion of equality, as implemented by the identity types \( a \overset{\sim}{\to} b \), is carefully engineered to accommodate notions of congruence and symmetry from diverse areas of mathematics, including geometry. Exposing that point of view in the context of geometry is the main point of this book.

In light of the analogy with geometry just introduced, we will refer to an element \( i \) of \( a \overset{\sim}{\to} a \) as a symmetry of \( a \). Think, for example, of a congruence of a triangle with itself. An example of a non-trivial symmetry will be seen in Exercise 2.13.3.

Consider the identity type \( \text{fact}(2) \overset{\sim}{\to} 2 \), where \( \text{fact} \) denotes the factorial function defined in Section 2.4. Expansion of the definitions in \( \text{fact}(2) \overset{\sim}{\to} 2 \) simplifies it to \( \text{succ}(\text{succ}(0)) \overset{\sim}{\to} \text{succ}(\text{succ}(0)) \), so we see from rule (E2) that \( \text{refl}_{\text{succ}(\text{succ}(0))} \) serves as an element of it.\(^{19}\) We may also write either \( \text{refl}_2 \) or \( \text{refl}_{\text{fact}(2)} \) for that element. A student might want a more detailed derivation that \( \text{fact}(2) \) may be identified with 2, but as a result of our convention above that definitions may be applied without changing anything, the application of definitions, including inductive definitions, is normally regarded as a trivial operation, and the details are usually omitted.

We will refer to rule (E3) as “induction for identity”. To signal that we wish to apply it, we may annouce that we argue by (path) induction on \( e \), or simply by path induction.

The family \( f \) resulting from an application of rule (E3) may be regarded as having been completely defined by the single declaration \( f(a, \text{refl}_a) \equiv p \), and indeed, we will often simply write such a declaration as a shorthand way of applying rule (E3). The rule says that to construct something from every identification \( e \) of \( a \) with something else, it suffices to consider the special case where the identification \( e \) is \( \text{refl}_a : a \overset{\sim}{\to} a \).\(^{20}\)

Intuitively, the induction principle for identity amounts to saying that the element \( \text{refl}_a \) “generates” the system of types \( a \overset{\sim}{\to} b \), as \( b \) ranges over elements of \( A \).\(^{21}\)

Equality relations are symmetric. For identity types we establish something similar, taking into account that the notion of equality implemented here keeps track of the way two things are identified, and there can be multiple ways. Given a type \( X \) and elements \( a \) and \( b \) of \( X \), we have an identity type \( a \overset{\sim}{\to} b \) of (zero or more) identifications of \( a \) with \( b \). We also have an identity type \( b \overset{\sim}{\to} a \) of identifications of \( b \) with \( a \). Symmetry now takes the form of a function from type \( a \overset{\sim}{\to} b \) to type \( b \overset{\sim}{\to} a \), intuitively reversing any identification of \( a \) with \( b \) to give an identification of \( b \) with \( a \). In order to produce an element of \( b \overset{\sim}{\to} a \) from an element \( e \) of \( a \overset{\sim}{\to} b \), for any \( b \) and \( e \), we argue by induction on \( e \). We let \( P(b, e) \) be \( b \overset{\sim}{\to} a \) for any \( b \) of type \( X \) and for any \( e \) of type \( a \overset{\sim}{\to} b \), for use in rule (E3) above. Application of rule (E3) reduces us to the case where \( b \) is \( a \) and \( p \) is \( \text{refl}_a \), and our task is now to produce an element of \( a \overset{\sim}{\to} a \); we choose \( \text{refl}_a \) for it.

Equality relations are also transitive. We proceed in a similar way as for symmetry. For each \( a, b, c : X \) and for each \( p : a \overset{\sim}{\to} b \) and for each \( q : b \overset{\sim}{\to} c \) we want to produce an element of type \( a \overset{\sim}{\to} c \). By induction on \( q \) we are reduced to the case where \( c \) is \( b \) and \( q \) is \( \text{refl}_b \), and we are to produce an element of \( a \overset{\sim}{\to} b \). The element \( p \) serves the purpose.

Now we state our symmetry result a little more formally.

\(^{19}\)We will see later that numbers only have trivial symmetries, so the possibility that there are other ways to identify \( \text{fact}(2) \) with 2 doesn’t arise.

\(^{20}\)Notice that the single special case in such an induction corresponds to the single way of introducing elements of identity types via rule (E2), and compare that with (P4), which dealt with the two ways of introducing elements of \( \mathbb{N} \).

\(^{21}\)We can also use a geometric intuition: when \( b \) “freely ranges” over elements of \( A \), together with a path \( e : a \overset{\sim}{\to} b \), while we keep the element \( a \) fixed, we can picture \( e \) as a piece of string winding through \( A \), and the “freeness” of the pair \( (b, e) \) allows us to pull the string \( e \), and \( b \) with it, until we have the constant path at \( a \), \( \text{refl}_a \). Conversely, we can imagine \( b \) starting at \( a \) and \( e \) starting out as \( \text{refl}_b \), and then think of \( b \) roaming throughout \( A \), pulling the string \( e \) along with it, until it finds every path from \( a \) to some other element.
**Definition 2.5.1.** For any type $X$ and for any $a, b : X$, let

$$\text{symm}_{a,b} : (a \simeq b) \to (b \simeq a)$$

be the function defined by induction by setting $\text{symm}_{a,a} (\text{refl}_a) \equiv \text{refl}_a$.

This operation on paths is called *path inverse*, and we may abbreviate $\text{symm}_{a,b} (p)$ as $p^{-1}$. \hfill $\square$

Similarly, we formulate transitivity a little more formally, as follows.

**Definition 2.5.2.** For any type $X$ and for any $a, b, c : X$, let

$$\text{trans}_{a,b,c} : (a \simeq b) \to ((b \simeq c) \to (a \simeq c))$$

be the function defined by induction by setting $(\text{trans}_{a,b,b}(p))(\text{refl}_b) \equiv p$.

This binary operation is called *path composition* or *path concatenation*, and we may abbreviate $(\text{trans}_{a,b,c}(p))(q)$ as either $p \cdot q$, or as $q \cdot p$, $(q p)$, or $q \circ p$. \hfill $\square$

The intuition that the path $p$ summarizes a gradual change from $a$ to $b$, and $q$ summarizes a gradual change from $b$ to $c$, leads to the intuition that $p \cdot q$ progresses gradually from $a$ to $c$ by first changing $a$ to $b$ and then changing $b$ to $c$; see Fig. 2.1.

The notation $q \circ p$ for path composition, with $p$ and $q$ in reverse order, fits our intuition particularly well when the paths are related to functions and the composition of the paths is related to the composition of the related functions in the same order, as happens, for example, in connection with *transport* (defined below in Definition 2.5.4) in Exercise 2.5.5.

The types of $\text{symm}_{a,b}$ and $\text{trans}_{a,b,c}$ express that $\simeq$ is symmetric and transitive. Another view of $\text{symm}_{a,b}$ and $\text{trans}_{a,b,c}$ is that they are operations on identifications, namely reversing an identification and concatenating two identifications. The results of various combinations of these operations can often be identified: we formulate some of these identifications in the following exercise.

**Exercise 2.5.3.** Let $X$ be a type and let $a, b, c, d : X$ be elements.

1. For $p : a \simeq b$, construct an identification of type $p \cdot \text{refl}_b \simeq p$.

2. For $p : a \simeq b$, construct an identification of type $\text{refl}_a \cdot p \simeq p$.

3. For $p : a \simeq b$, $q : b \simeq c$, and $r : c \simeq d$, construct an identification of type $(p \cdot q) \cdot r \simeq p \cdot (q \cdot r)$.

4. For $p : a \simeq b$, construct an identification of type $p^{-1} \cdot p \simeq \text{refl}_b$.

5. For $p : a \simeq b$, construct an identification of type $p \cdot p^{-1} \simeq \text{refl}_a$.

6. For $p : a \simeq b$, construct an identification of type $(p^{-1})^{-1} \simeq p$. \hfill $\square$

Given an element $p : a \simeq a$, we may use concatenation to define powers $p^n : a \simeq a$ by induction on $n : \mathbb{N}$; we set $p^0 \equiv \text{refl}_a$ and $p^{n+1} \equiv p \cdot p^n$. Negative powers $p^{-n}$ are defined as $(p^{-1})^n$. \hfill 22

One frequent use of elements of identity types is in *substitution*, which is the logical principle that supports our intuition that when $x$ can be identified with $y$, we may replace $x$ by $y$ in mathematical expressions at will. A wrinkle new to students will likely be that, in our logical framework where there may be various ways to identify $x$ with $y$, one must specify the identification used in the substitution. Thus one may...
prefer to speak of using an identification to transport properties and data about \( x \) to properties and data about \( y \).

Here is a geometric example: if \( x \) is a triangle of area 3 in the plane, and \( y \) is congruent to \( x \), then \( y \) also has area 3.

Here is another example: if \( x \) is a right triangle in the plane, and \( y \) is congruent to \( x \), then \( y \) is also a right triangle, and the congruence informs us which of the 3 angles of \( y \) is the right angle.

Now we introduce the notion more formally.

**Definition 2.5.4.** Let \( X \) be a type, and let \( T(x) \) be a family of types parametrized by a variable \( x : X \) (as discussed in Section 2.2). Suppose \( a, b : X \) and \( e : a \rightsquigarrow b \). Then we may construct a function of type \( T(a) \to T(b) \). The function

\[
\operatorname{trp}_e^T : T(a) \to T(b)
\]

is defined by induction setting \( \operatorname{trp}_e^T \equiv \operatorname{id}_{T(a)} \).

The function thus defined may be called the **transport function in the type family** \( T \) along the path \( e \), or, less verbosely, **transport**.\(^\text{23}\) We may also simplify the notation to just \( \operatorname{trp}_e \). The transport functions behave as expected: we may construct an identification of type \( \operatorname{trp}_e \equiv \operatorname{trp}_{e'} \). In words: transport along the composition \( e \circ e' \) can be identified with the composition of the two transport functions. This may be proved by induction in the following exercise.

**Exercise 2.5.5.** Let \( X \) be a type, and let \( T(x) \) be a family of types parametrized by a variable \( x : X \). Suppose we are given elements \( a, b, c : X, e : a \rightsquigarrow b \), and \( e' : b \rightsquigarrow c \). Construct an identification of type

\[
\operatorname{trp}_{e'e} \equiv \operatorname{trp}_e \circ \operatorname{trp}_{e'}.
\]

Yet another example of good behavior is given in the following exercise.

**Exercise 2.5.6.** Let \( X, Y \) be types. As discussed in Section 2.2, we may regard the expression \( Y \) as a constant family of types parametrized by a variable \( x : X \). Produce an identification of type \( \operatorname{trp}_p^Y \equiv \operatorname{id}_Y \), for any path \( p : a \rightsquigarrow b \).

In Section 2.15 below we will discuss what it means for a type to have at most one element. When the types \( T(x) \) may have more than one element, we may regard an element of \( T(x) \) as providing additional structure on \( x \). In that case, we will refer to the transport function \( \operatorname{trp}_e : T(a) \to T(b) \) as transport of structure from \( a \) to \( b \).

Take, for example, \( T(x) \equiv (x \to x) \). Then \( \operatorname{trp}_e \) is of type \( (a \rightsquigarrow a) \to (b \rightsquigarrow b) \) and transports a symmetry of \( a \) to a symmetry of \( b \).

By contrast, when the types \( T(x) \) have at most one element, we may regard an element of \( T(x) \) as providing a proof of a property of \( x \). In that case, the transport function \( \operatorname{trp}_e : T(a) \to T(b) \) provides a way to establish a claim about \( b \) from a claim about \( a \), so we will refer to it as substitution. In other words, elements that can be identified have the same properties.

### 2.6 Product types

Functions and product types have been introduced in Section 2.2, where we have also explained how to create a function by enclosing a family of
elements in one. In this section we treat functions and product types in more detail.

Recall that if $X$ is a type and $Y(x)$ is a family of types parametrized by a variable $x$ of type $X$, then there is a product type\footnote{Also known as a Pi-type.} $\prod_{x : X} Y(x)$ whose elements $f$ are functions that provide elements $f(a)$ of type $Y(a)$, one for each $a : X$. We will refer to $X$ as the parameter type of the product. By contrast, if $Y$ happens to be a constant family of types, then $\prod_{x : X} Y$ will also be denoted by $X \to Y$, and it will also be called a function type.

If $X$ and $Y(x)$ are elements of a universe $\UU$, then so is $\prod_{x : X} Y(x)$.

Functions preserve identity, and we will use this frequently later on. More precisely, functions induce maps on identity types, as the following definition makes precise.

**Definition 2.6.1.** For all types $X, Y$, functions $f : X \to Y$ and elements $x, x' : X$, the function

$$\text{ap}_{f, x, x'} : (x \xrightarrow{\alpha} x') \to (f(x) \xrightarrow{\alpha} f(x'))$$

is defined by induction by setting $\text{ap}_{f, x, x} : (\text{refl}_x) \equiv \text{refl}_{f(x)}$.

The function $\text{ap}_{f, x, x'}$, for any elements $x$ and $x'$ of $X$, is called an application of $f$ to paths or to identifications, and this explains the choice of the symbol ap in the notation for it. It may also be called the function (or map) induced by $f$ on identity types.

When $x$ and $x'$ are clear from the context, we may abbreviate $\text{ap}_{f, x, x'}$ by writing $\text{ap}_f$ instead. For convenience, we may abbreviate it even further, writing $f(p)$ for $\text{ap}_f(p)$.

The following lemma shows that $\text{ap}_f$ is compatible with composition.

**Construction 2.6.2.** Given a function $f : X \to Y$, and elements $x, x', x'' : X$, and paths $p : x \xrightarrow{\alpha} x'$ and $p' : x' \xrightarrow{\alpha} x''$, we have an identification of type $\text{ap}_f(p' \cdot p) \xrightarrow{\alpha} \text{ap}_f(p') \cdot \text{ap}_f(p)$.

Similarly, we have that $\text{ap}_f$ is compatible with path inverse in that we have an identification of type $\text{ap}_f(p^{-1}) \xrightarrow{\alpha} (\text{ap}_f(p))^{-1}$ for all $p : x \xrightarrow{\alpha} x'$.

Finally, we have an identification of type $\text{ap}_{\text{id}}(p) \xrightarrow{\alpha} p$ for all $p : x \xrightarrow{\alpha} x'$.

**Implementation of Construction 2.6.2.** By induction on $p$ and $p'$, one reduces to producing an identification of type $\text{ap}_f(\text{refl}_x \cdot \text{refl}_x) \xrightarrow{\alpha} \text{ap}_f(\text{refl}_x) \cdot \text{ap}_f(\text{refl}_x)$.

Both $\text{ap}_f(\text{refl}_x \cdot \text{refl}_x)$ and $\text{ap}_f(\text{refl}_x) \cdot \text{ap}_f(\text{refl}_x)$ are equal to $\text{refl}_{f(x)}$ by definition, so the identification $\text{refl}_{f(x)}$ has the desired type.

The other two parts of the construction are also easily done by induction on $p$.\hfill $\Box$

**Exercise 2.6.3.** Let $X$ be a type and $T(x)$ a family of types parametrized by a variable $x : X$. Furthermore, let $A$ be a type, let $f : A \to X$ be a function, let $a$ and $a'$ be elements of $A$, and let $p : a \xrightarrow{\alpha} a'$ be a path. Verify that the two functions $\text{trp}_{\text{ap}_f/p}(\text{refl}_x)$ and $\text{trp}_{\text{ap}_f}(\text{refl}_x)$ are of type $T(f(a)) \to T(f(a'))$.

Then construct an identification between them, i.e., construct an element of type $\text{trp}_{\text{ap}_f/p} \xrightarrow{\alpha} \text{trp}_{\text{ap}_f}(p)$.

If two functions $f$ and $g$ of type $\prod_{x : X} Y(x)$ can be identified, then their values can be identified, i.e., for every element $x$ of $X$, we may produce an identification of type $f(x) \xrightarrow{\alpha} g(x)$, which can be constructed by induction, as follows.
Definition 2.6.4. Let \( f, g : \prod_{x : X} Y(x) \). Define the function

\[
\text{ptw}_{f,g} : (f \overset{x}{\rightarrow} g) \rightarrow \left( \prod_{x : X} f(x) \overset{x}{\rightarrow} g(x) \right),
\]

by induction by setting \( \text{ptw}_{f,f}(\text{refl}_f) \equiv x \mapsto \text{refl}_{f(x)} \). \( ^{25} \)

Conversely, given \( f, g : \prod_{x : X} Y(x) \), from a basic axiom called function extensionality, postulated below in Principle 2.9.17, an identification \( f \overset{x}{\rightarrow} g \) can be produced from a family of identifications of type \( f(x) \overset{x}{\rightarrow} g(x) \) parametrized by a variable \( x \) of type \( X \).

Definition 2.6.5. Let \( X, Y \) be types and \( f, g : X \rightarrow Y \) functions. Given an element \( h \) of type \( \prod_{x : X} f(x) \overset{x}{\rightarrow} g(x) \), elements \( x \) and \( x' \) of \( X \), and a path \( p : x \overset{x}{\rightarrow} x' \), we have two elements \( h(x') \cdot \text{ap}_f(p) \) and \( \text{ap}_g(p) \cdot h(x) \) of type \( f(x) \overset{x}{\rightarrow} g(x) \). We construct an identification

\[
\text{ns}(h, p) : \left( h(x') \cdot \text{ap}_f(p) \overset{x}{\rightarrow} \text{ap}_g(p) \cdot h(x) \right),
\]

between them by induction, by setting \( \text{ns}(h, \text{refl}_a) \) to be some element of \( h(x) \cdot \text{refl}_{f(x)} \overset{x}{\rightarrow} h(x) \), which can be constructed by induction, as in Exercise 2.5.3. The type of \( \text{ns}(h, p) \) can be depicted as a square\( ^{26} \) and \( \text{ns}(h, p) \) is called a naturality square.

### 2.7 Identifying elements in members of families of types

If \( Y(x) \) is a family of types parametrized by a variable \( x \) of type \( X \), and \( a \) and \( a' \) are elements of type \( X \), then after identifying \( a \) with \( a' \) it turns out that it is possible to “identify” an element of \( Y(a) \) with an element of \( Y(a') \), in a certain sense. That is the idea of the following definition.

Definition 2.7.1. Suppose we are given a type \( X \) in a universe \( \mathcal{U} \) and a family of types \( Y(x) \), also in \( \mathcal{U} \), parametrized by a variable \( x \) of type \( X \). Given elements \( a, a' : X, y : Y(a) \), and \( y' : Y(a') \) and a path \( p : a \overset{x}{\rightarrow} a' \), we define a new type \( y \overset{p}{\rightarrow} y' \) in \( \mathcal{U} \) as follows. We proceed by induction on \( a' \) and \( p \), which reduces us to the case where \( a' \) is \( a \) and \( p \) is \( \text{refl}_a \), rendering \( y \) and \( y' \) of the same type \( Y(a) \) in \( \mathcal{U} \), allowing us to define \( y \overset{\text{refl}_a}{\rightarrow} y' \) to be \( y \overset{p}{\rightarrow} y' \), which is also in \( \mathcal{U} \). \( ^{26} \)

Remark 2.7.2. TODO: what if the \( \mathcal{U} \)'s above are different? Also: a remark/exercise about the special case where \( Y \) is the constant family. \( ^{26} \)

An element \( q : y \overset{p}{\rightarrow} y' \) is called an identification of \( y \) with \( y' \) over \( p \), or a path from \( y \) to \( y' \) over \( p \). Intuitively, we regard \( p \) as specifying a way for \( a \) to change gradually into \( a' \), and this provides a way for \( Y(a) \) to change gradually into \( Y(a') \); then \( q \) charts a way for \( y \) to change gradually into \( y' \) as \( Y(a) \) changes gradually into \( Y(a') \). \( ^{27} \)

The following definition identifies the type of paths over \( p \) with a type of paths using transport along \( p \).

Definition 2.7.3. In the context of Definition 2.7.1, define by induction on \( p \) an identification \( \text{po}_p : \left( y \overset{p}{\rightarrow} y' \right) \overset{p}{\rightarrow} \left( \text{tr}_p(y) \overset{p}{\rightarrow} y' \right) \) in \( \mathcal{U} \), by setting \( \text{po}_{\text{refl}_p} \equiv \text{refl}_{Y \overset{p}{\rightarrow} Y'} \).

Many of the operations on paths have counterparts for paths over paths. For example, we may define composition of paths over paths as follows.

\( ^{25} \) The notation \( \text{ptw} \) is chosen to remind the reader of the word “point-wise”, because the identifications are provided just for each point \( x \). An alternative approach goes by considering, for any \( x : X \), the evaluation function \( \text{ev}_x : \prod_{x : X} Y(x) \rightarrow Y(x) \) defined by \( \text{ev}_x(f) = f(x) \). Then one could define \( \text{ptw}_{f,g}(p, x) \equiv \text{ap}_{\text{ev}_x}(p) \). The functions provided by these two definitions are not equal by definition, but they can be identified, and one can easily be used in place of the other.

\( ^{26} \) We picture this as follows: the path from \( y \) to \( y' \) over \( p \) travels through the vertical lines representing the types \( Y(x) \) as \( x : X \) moves along the path \( p \) in \( X \) from \( a \) to \( a' \).
**Definition 2.7.4.** Suppose we are given a type \( X \) and a family of types \( Y(x) \) parametrized by the elements \( x \) of \( X \). Suppose also that we have elements \( x, x', x'' : X \), a path \( p : x \to x' \), and a path \( p' : x' \to x'' \). Suppose further that we have elements \( y : Y(x) \), \( y' : Y(x') \), and \( y'' : Y(x'') \), with paths \( q : y \to y' \) over \( p \) and \( q' : y' \to y'' \) over \( p' \). Then we define the composite path \( (q' \circ q) : y \to y'' \) over \( p' \circ p \) as follows. First we apply path induction on \( p' \) to reduce to the case where \( x'' \) is \( x' \) and \( p' \) is \( \text{refl}_p \). That also reduces the type \( y' \to y'' \) to the identity type \( y' \to y'' \), so we may apply path induction on \( q' \) to reduce to the case where \( y'' \) is \( y' \) and \( q' \) is \( \text{refl}_{p'} \). Now observe that \( p' \circ p = p \), so \( q \) provides the element we need.

Similarly, one can define the inverse of a path over a path, writing \( q^{-1} : y' \to y \) for the inverse of \( q : y \to y' \). For these operations on paths over paths we have identifications analogous to those for the operations on paths in Exercise 2.5.3, after some modification. For example, \( g^{-1} \circ q \) of type \( y \to y' \) and \( \text{refl}_y \) of type \( y \to y \) cannot be directly used to form an identity type, since their types are not equal by definition. We will state these identifications when we need them.

**Exercise 2.7.5.** Try to state some of these identifications yourself.

The following construction shows how to handle application of a dependent function \( f \) to paths using the definition above.

**Definition 2.7.6.** Suppose we are given a type \( X \), a family of types \( Y(x) \) parametrized by the elements \( x \) of \( X \), and a function \( f : \prod_{x : X} Y(x) \). Given elements \( x, x' : X \) and a path \( p : x \to x' \), we define

\[
\text{apd}_f(p) : f(x) \to f(x')
\]

by induction on \( p \), setting

\[
\text{apd}_f(\text{refl}_x) \equiv \text{refl}_{f(x)}.
\]

The function \( \text{apd}_f \) is called dependent application of \( f \) to paths.\(^{28}\) For convenience, we may abbreviate \( \text{apd}_f(p) \) to \( f(p) \), when there is no risk of confusion.

The following construction shows how functions of two variables may be applied to paths over paths.

**Definition 2.7.7.** Suppose we are given a type \( X \), a family of types \( Y(x) \) parametrized by the elements \( x \) of \( X \), and a type \( Z \). Suppose also we are given a function \( g : \prod_{x : X} Y(x) \to Z \) of two variables. Given elements \( x, x' : X, y : Y(x), \text{and} \ y' : Y(x') \), a path \( p : x \to x' \), and a path \( q : y \to y' \) over \( p \), we may construct a path

\[
\text{apap}_{g}(p)(q) : g(x)(y) \to g(x')(y')
\]

by induction on \( p \) and \( q \), setting

\[
\text{apap}_{g}(\text{refl}_x)(\text{refl}_y) \equiv \text{refl}_{g(x)(y)}.
\]

The function \( p \mapsto q \mapsto \text{apap}_{g}(p)(q) \) is called application of \( g \) to paths over paths. For convenience, we may abbreviate \( \text{apap}_{g}(p)(q) \) to \( g(p)(q) \).

The following definition will be useful later.

---

\(^{28}\)We picture \( f \) via its graph of the values \( f(x) \) as \( x \) varies in \( X \). The dependent application of \( f \) to \( p \) is then the piece of the graph that lies over \( p \):
**Definition 2.7.8.** Suppose we are given a type \( X \), a family of types \( Y(x) \) parametrized by the elements \( x \) of \( X \), and a type \( Z \). Suppose also we are given a function \( g : \prod_{x:X} Y(x) \to Z \) of two variables. Given an element \( x : X \), elements \( y, y' : Y(x) \), and an identification \( q : y \cong y' \), then we define an identification of type \( \text{ap}_g(\text{refl}_x)(q) \cong \text{ap}_g(\text{refl}_x)(q') \) by induction on \( q \), thereby reducing to the case where \( y' \) is \( y \) and \( q \) is \( \text{refl}_y \), rendering the two sides of the equation equal, by definition, to \( \text{refl}_{Y(x)(y)} \).

### 2.8 Sum types

There are *sums* of types. By this we mean if \( X \) is a type and \( Y(x) \) is a family of types parametrized by a variable \( x \) of type \( X \), then there will be a type\(^{29}\) \( \sum_{x : X} Y(x) \) whose elements are all pairs \((a, b)\), where \( a : X \) and \( b : Y(a) \). Since the type of \( b \) may depend on \( a \), we also call such a pair a dependent pair. We may refer to \( X \) as the *parameter type* of the sum.\(^{30}\)

If \( X \) and \( Y(x) \) are elements of a universe \( \mathcal{U} \), then so is \( \sum_{x : X} Y(x) \).

Proving something about (or constructing something from) every element of \( \sum_{x : X} Y(x) \) is done by performing the construction on elements of the form \((a, b)\), for every \( a : X \) and \( b : Y(a) \). Two important examples of such constructions are:

1. *first projection*, \( \text{fst} : (\sum_{x : X} Y(x)) \to X \), \( \text{fst}(a, b) \equiv a \);
2. *second projection*, \( \text{snd}(a, b) : Y(a) \), \( \text{snd}(a, b) \equiv b \).

In (2), the type of \( \text{snd} \) is, in full, \( \prod_{z : \sum_{x : X} Y(x)} Y(\text{fst}(z)) \).

**Remark 2.8.1.** An important special case of sum types is when the type \( Y(x) \) does not depend on \( x : X \). In that case the sum type \( \sum_{x : X} Y(x) \) is denoted as \( X \times Y \) and called a *binary product type*, see Section 2.11.

**Remark 2.8.2.** One may consider sums of sums. For example, suppose \( X \) is a type, suppose \( Y(x) \) is a family of types parametrized by a variable \( x \) of type \( X \), and suppose \( Z(x, y) \) is a family of types parametrized by variables \( x : X \) and \( y : Y(x) \). In this case, the *iterated sum* \( \sum_{x : X} \sum_{y : Y(x)} Z(x, y) \) consists of pairs of the form \((x, y, z)\). For simplicity, we introduce the notation \((x, y, z) \equiv (x, (y, z))\), and refer to \((x, y, z)\) as a *triple* or as a 3-tuple.

That process can be repeated: suppose \( X_1 \) is a type, suppose \( X_2(x_1) \) is a family of types parametrized by a variable \( x_1 \) of type \( X_1 \), suppose \( X_3(x_1, x_2) \) is a family of types parametrized by variables \( x_1 : X_1 \) and \( x_2 : X_2(x_1) \), and so on, up to a family \( X_n(x_1, \ldots, x_{n-1}) \) of types. In this case, the *iterated sum* \( \sum_{x_1 : X_1} \sum_{x_2 : X_2(x_1)} \cdots \sum_{x_{n-1} : X_{n-1}(x_1, \ldots, x_{n-2})} X_n(x_1, \ldots, x_{n-1}) \) consists of elements of the form \((x_1, (x_2, (\ldots (x_{n-1}, x_n)) \ldots))\); each such element is a pair whose second member is a pair, and so on, so we may refer to it as an *iterated pair*. For simplicity, we introduce the notation \((x_1, x_2, \ldots, x_n)\) for such an iterated pair, and refer to it as an *n-tuple*.

\(^{29}\)Also known as a *Sigma-type*.

\(^{30}\)We may denote \( \sum_{x : X} Y(x) \) by \( \text{Tot}(Y) \) and also call it the *total type* of the family \( Y(x) \). We can picture it, in the style of the pictures above, as the entire blob lying over \( X \). (Each \( Y(x) \) is a vertical line over \( x : X \), and a point \( y : Y(x) \) becomes a point \((x, y)\) in the blob.)

![Diagram](https://via.placeholder.com/150)

Another example of an iterated sum is when \( Z(u) \) is a family of types parametrized by a variable \( u \) of type \( \sum_{x : X} Y(x) \). Elements of the type \( \sum_{u : \sum_{x : X} Y(x)} Z(u) \) are triples \(((x, y), z)\). We use the triple-notation also for this case.
2.9 Equivalences

Using a combination of sum, product, and identity types allows us to express important notions, as done in the following definitions.

The property that a type $X$ has “exactly one element” may be made precise by saying that $X$ has an element such that every other element is equal to it. This property is encoded in the following definition.

**Definition 2.9.1.** Given a type $X$, define a type $\text{isContr}(X)$ by setting

$$\text{isContr}(X) \equiv \sum_{c : X} \prod_{x : X} (c \rightarrow x).$$

If $(c, h) : \text{isContr}(X)$, then $c$ will be called the center of the contraction $h$, and we call the type $X$ contractible.

By path composition, one sees that any element $x : X$ can serve as the center of a contraction of a contractible type $X$.

The following lemma gives an important example of a contractible type.

**Lemma 2.9.2.** For any type $X$ and $a : X$, the singleton type $\sum_{x : X} (a \rightarrow x)$ consists of pairs $(x, i)$ with $i : a \rightarrow x$. The following lemma shows that a singleton type has exactly one element, justifying the name.

**Proof.** Take as center the pair $(a, \text{refl}_a)$. We have to produce, for any element $x$ of $X$ and for any identification $i : a \rightarrow x$, an identification of type $(a, \text{refl}_a) \rightarrow (x, i)$. This is done by path induction on $i$, which reduces us to producing an identification of type $(a, \text{refl}_a) \rightarrow (a, \text{refl}_a)$; reflexivity provides one, namely $\text{refl}_{(a,\text{refl}_a)}$.

**Definition 2.9.3.** Given a function $f : X \rightarrow Y$ and an element $y : Y$, the fiber (or preimage) $f^{-1}(y)$ is encoded by defining

$$f^{-1}(y) \equiv \sum_{x : X} (y \rightarrow f(x)).$$

In other words, an element of the fiber $f^{-1}(y)$ is a pair consisting of an element $x$ of $X$ and an identification of type $y \rightarrow f(x)$.

In set theory, a function $f : X \rightarrow Y$ is a bijection if and only if all preimages $f^{-1}(y)$ consist of exactly one element. We can also express this in type theory, in a definition due to Voevodsky, for types in general.

**Definition 2.9.4.** A function $f : X \rightarrow Y$ is called an equivalence if $f^{-1}(y)$ is contractible for all $y : Y$. The condition is encoded by the type

$$\text{isEquiv}(f) \equiv \prod_{y : Y} \text{isContr}(f^{-1}(y)).$$

We may say that $X$ and $Y$ are equivalent if we have an equivalence between them.

**Definition 2.9.5.** We define the type $X \equiv Y$ of equivalences from $X$ to $Y$ by the following definition.

$$(X \equiv Y) \equiv \sum_{f : X \rightarrow Y} \text{isEquiv}(f).$$
Suppose \( f : X \to Y \) is an equivalence, and let \( t(y) : \text{isContr}(f^{-1}(y)) \), for each \( y : Y \), be the corresponding witness to contractibility of the fiber. Using \( t \) we can define an inverse function \( g : Y \to X \) by setting \( g(y) :≡ \text{fst}(\text{fst}(t(y))) \). This can be seen as follows.

By unfolding all the definitions\(^{31}\), we have an identification of type
\[
f(g(y)) \to y.\]

Moreover, \((x, \text{refl}_{f(x)})\) is an element of the fiber \( f^{-1}(f(x)) \), and \( t(f(x)) \) is a proof that this fiber is contractible. Hence the center of contraction \( \text{fst}(t(f(x))) \) is identified with \((x, \text{refl}_{f(x)})\), and so \( g(f(x)) \equiv (\text{fst}(\text{fst}(t(f(x))) )) \to x \).

We have shown that \( f \) and \( g \) are inverse functions. When it won’t cause confusion with the notation for the fibers of \( f \), we will write \( f^{-1} \) instead of \( g \).

For any type \( X \), the identity function \( \text{id}_X \) is an equivalence from \( X \) to \( X \).

To see that, observe that for every element \( a \) in \( X \), \( \text{id}_X^{-1}(a) \) is a singleton type and hence is contractible. This observation, combined with the fact that \( \text{trp}^r_{\text{refl}} \equiv \text{id}_T^{(r)} \), gives that the function \( \text{trp}^r \) from Definition 2.5.4 is an equivalence from \( T(x) \) to \( T(y) \), for all \( e : x \to y \).

**Exercise 2.9.6.** Make sure you understand the two applications of \( \text{fst} \) in the definition \( f^{-1}(y) \equiv \text{fst}(\text{fst}(t(y))) \) above. Show that \( f^{-1} \) is an equivalence from \( Y \) to \( X \). Give a function \( (X \to Y) \to (Y \to X) \).

**Exercise 2.9.7.** Give a function \( (X \to Y) \to ((Y \to Z) \to (X \to Z)) \).

**Exercise 2.9.8.** Consider types \( A, B, \) and \( C \), functions \( f : A \to B \), \( g : A \to C \) and \( h : B \to C \), together with an element \( e : h f \to g \).

We have shown that \( f \) and \( g \) are inverse functions. When it won’t cause confusion with the notation for the fibers of \( f \), we will write \( f^{-1} \) instead of \( g \).

**Construction 2.9.9.** Let \( X, Y \) be types. For each equivalence \( f : X \to Y \), we have a function \( g : Y \to X \) such that for all \( x : X \) we have \( g(f(x)) \to x \) and for all \( y : Y \) we have \( f(g(y)) \to y \).

**Implementation of Construction 2.9.9.** Given an equivalence \( f : X \to Y \) we can take \( g :≡ f^{-1} \). For the converse, see Chapter 4 of the HoTT Book\(^{32}\) or \texttt{isweq.iso}.

We put Construction 2.9.9 immediately to good use.

**Lemma 2.9.10.** Let \( X \) be a type with element \( a \), and let \( B(x, i) \) be a type for all \( x : X \) and \( i : a \to x \). Define \( f(x, i) : B(x, i) \to B(a, \text{refl}_a) \) by induction on \( i \), setting \( f(a, \text{refl}_a, b) \equiv b \) for all \( b : B(a, \text{refl}_a) \). Then \( f \) defines an equivalence
\[
f : \sum_{x : X} \sum_{i : a \to x} B(x, i) \to B(a, \text{refl}_a).
\]

**Proof.** We can also define \( g : B(a, \text{refl}_a) \to \sum_{x : X} \sum_{i : a \to x} B(x, i) \) mapping \( b : B(a, \text{refl}_a) \) to \((a, \text{refl}_a, b)\). Clearly \( f(g(b)) \to b \) for all \( b : B(a, \text{refl}_a) \).

Moreover, \( g(f(x, i, b)) \to (x, i, b) \) is clear by induction on \( i \), for all \( b : B(x, i) \).

By Construction 2.9.9 it follows that \( f \) is an equivalence.

The above lemma clearly reflects the contractibility of the singleton type \( \sum_{x : X}(a \to x) \).\(^{33}\) For this reason we call application of this lemma ‘to contract away’ the prefix \( \sum_{x : X} \sum_{i : a \to x} \), in order to obtain a simpler type. It is often applied in the following simpler form.

\(^{31}\)Note that \( \text{fst}(t(y)) : f^{-1}(y) \), so \( \text{fst}(\text{fst}(t(y))) : X \) with \( \text{snd}(\text{fst}(t(y))) : y \to f(\text{fst}(\text{fst}(t(y)))) \).

\(^{33}\)In fact, an alternative proof would go as follows: First, we use Construction 2.9.9 to construct an element of \( \sum_{x : X} \sum_{y : Y(x)} Z(x, y) \to \sum_{w : \sum_{x : X} \sum_{y : Y(x)} Z(x, y)} \text{fib}(w, \text{snd}(w)) \), i.e., the associativity of sum types, where \( X \) is a type, \( Y(x) \) is a family of types depending on \( x : X \), and \( Z(x, y) \) is a family of types depending on \( x : X \) and \( y : Y(x) \). Then, we construct for any contractible type \( X \) and for any family of types \( Y(x) \) depending on \( x : X \), an equivalence between \( \sum_{x : X} Y(x) \) and \( Y(c) \), where \( c \) is the center of contraction of \( X \).
Corollary 2.9.11. With conditions as above, but with \( B \) not depending on \( i \), the same \( f \) establishes an equivalence
\[
\sum_{x:X} ((a \equiv x) \times B(x)) \equiv B(a).
\]

In the direction of further generality, we offer the following exercise.

Exercise 2.9.12. Suppose \( X, Y \) are types related by an equivalence \( f:X \to Y \). Let \( B(x) \) be a type for all \( x:X \). Construct an equivalence between 
\[
\sum_{x:X} B(x) \text{ and } \sum_{y:Y} B(f^{-1}(y)).
\]

We proceed now to define the notion of fiberwise equivalence.

Definition 2.9.13. Let \( X \) be a type, and let \( Y(x), Z(x) \) be families of types parametrized by \( x:X \). A map \( f \) of type \( \prod_{x:X} (Y(x) \to Z(x)) \) can be viewed as a family of maps \( f(x): Y(x) \to Z(x) \) and is called a fiberwise map. The totalization of \( f \) is defined by \( \operatorname{tot}(f)(x,y) \equiv (x,f(x)(y)) \). Using the denotation \( \operatorname{Tot}() \) for the total type of a type family we thus have
\[
\operatorname{tot}(f): \operatorname{Tot}(Y) \to \operatorname{Tot}(Z).
\]

Lemma 2.9.14. Let conditions be as in Definition 2.9.13. If \( f(x): Y(x) \to Z(x) \) is an equivalence for every \( x:X \) (we say that \( f \) is a fiberwise equivalence), then \( \operatorname{tot}(f) \) is an equivalence.

Proof. If \( f(x): Y(x) \to Z(x) \) is an equivalence for all \( x \) in \( X \), then the same is true of all \( f(x)^{-1}: Z(x) \to Y(x) \). Then we have the totalization \( \operatorname{tot}(x \mapsto f(x)^{-1}) \), which can easily be proved to be an inverse of \( \operatorname{tot}(f) \) (see the next exercise). Now apply Construction 2.9.9.

Exercise 2.9.15. Complete the details of the proof of Lemma 2.9.14.

We will allow ourselves to drop the “fiberwise” and talk simply about maps and equivalences between type families.

Exercise 2.9.16. Continuing with the setup of Definition 2.9.13, if \( \operatorname{tot}(f) \) is an equivalence, then \( f \) is a fiberwise equivalence.

For a proof see Theorem 4.7.7 of the HoTT Book

Yet another application of the notion of equivalence is to postulate axioms.

Principle 2.9.17. The axiom of function extensionality postulates that the function \( \operatorname{ptw}_{f,g}: (f \equiv g) \to \prod_{x:X} f(x) \equiv g(x) \) in Definition 2.6.4 is an equivalence. Formally, we postulate the existence of an element \( \operatorname{funext} : \operatorname{isEquiv}(\operatorname{ptw}_{f,g}) \). From that we can construct the corresponding inverse function
\[
\operatorname{ptw}_{f,g}^{-1}: \left( \prod_{x:X} f(x) \equiv g(x) \right) \to (f \equiv g).
\]

Thus two functions whose values can all be identified can themselves be identified. This supports the intuition that there is nothing more to a function than the values it sends its arguments to.

Exercise 2.9.18. Let \( X \) be a type. Construct an equivalence of type \( (\mathbf{true} \to X) \equiv X \).

Exercise 2.9.19. Let \( X \) be a type, and regard \( \mathbf{true} \) as a constant family of types over \( X \). Construct an equivalence of type \( \left( \sum_{x:X} \mathbf{true} \right) \equiv X \).
We start with a definition.

Exercise 2.9.20. Let X and Y be types, and let Z(y) be a type parameterized by y : Y. Construct an equivalence of type \( X \times \sum_{y : Y} Z(y) \xrightarrow{\sim} \sum_{y : Y} (X \times Z(y)). \)

Exercise 2.9.21. Let X and Y be types, and let Z(x, y) be a type parameterized by x : X and y : Y. Construct an equivalence of type \( \Sigma_{x : X} \sum_{y : Y} Z(x, y) \xrightarrow{\sim} \sum_{y : Y} \Sigma_{x : X} Z(x, y). \)

Exercise 2.9.22. Let X, Y and Z be types. Given functions \( f : X \to Y \) and \( g : Y \to Z \), construct a family of equivalences of type \( (g f)^{-1}(z) \xrightarrow{\sim} \sum_{w : Y \to Z} f^{-1}(\text{fap} w) \) parameterized by \( z : Z \). Hint: use Footnote 33.

Exercise 2.9.23. Let X, Y and Z be types. Given functions \( f : X \to Z \) and \( g : Y \to Z \), construct an equivalence of type \( \prod_{x : X} \sum_{y : Y} f(x) \xrightarrow{\sim} g(y) \). Hint: use Principle 2.9.17.

2.10 Identifying pairs

The identity type of two elements of \( \sum_{x : X} Y(x) \) is inductively defined in Section 2.5, as for any other type, but one would like to express the identity type for pairs in terms of identifications in the constituent types. This would explain better what it means for two pairs to be identified. We start with a definition.

Definition 2.10.1. Suppose we are given a type \( X \) and a family of types \( Y(x) \) parametrized by the elements \( x \) of \( X \). Consider the function

\[
\text{pair} : \prod_{x : X} \left( Y(x) \to \sum_{x' : X} Y(x') \right)
\]

defined by

\[
\text{pair}(x)(y) := (x, y).
\]

For any elements \( (x, y) \) and \( (x', y') \) of \( \sum_{x : X} Y(x) \), we define the map

\[
\left( \sum_{p : x \to x'} y \xrightarrow{p} y' \right) \to (x, y) \xrightarrow{\sim} (x', y')
\]

by

\[
(p, q) \mapsto \text{apap}_{\text{pair}}(p)(q).
\]

(Refer to Definition 2.7.1 for the meaning of the type \( y \xrightarrow{p} y' \), and to Definition 2.7.7 for the definition of \( \text{apap} \).

We picture paths between pairs much in the same way as paths over paths, cf. Footnote 27. Just as, to give a pair in the sum type \( \sum_{x : X} Y(x) \), we need both the point \( x \) in the parameter type \( X \) as well as the point \( y \) in \( Y(x) \), to give a path from \((x, y)\) to \((x', y')\), we need both a path \( p : x \to x' \) as well as a path \( q : y \to y' \) over \( p \). Here’s a similar picture, where we depict the types in the family as being 2-dimensional for a change.

Construction 2.10.2. In the situation of Definition 2.10.1, if \( x' \) is \( x \), so that we have \((y \xrightarrow{\text{refl}_{x'}} y') \equiv (y \xrightarrow{p} y')\), then for any \( q : y \to y' \), we can construct an identification of type:

\[
(\text{refl}_{x', q}) \xrightarrow{\sim} \text{ap}_{\text{pair}}(p) q
\]

Implementation of Construction 2.10.2. By induction on \( q \) it suffices to establish an identification

\[
(\text{refl}_{x', \text{refl}_{y}}) \xrightarrow{\sim} \text{ap}_{\text{pair}}(\text{refl}_{y}),
\]

both sides of which are equal to \( \text{refl}_{(x', y)} \) by definition.

The following lemma gives the desired characterization of paths between pairs.
There is special case of sum types that deserves to be mentioned since it occurs quite often. Let \( X \) and \( Y \) be types, and consider the constant family of types \( Y(x) \equiv Y \). In other words, \( Y(x) \) is a type that depends on an element \( x \) of \( X \) that happens to be \( Y \) for any such \( x \). (Recall Exercise 2.5.6.) Then we can form the sum type \( \sum_{x : X} Y(x) \) as above. Elements of this sum type are pairs \((x, y)\) with \( x \) in \( X \) and \( y \) in \( Y(x) \equiv Y \). In this case the type of \( y \) doesn’t depend on \( x \), and in this special case the sum type is called the binary product, or cartesian product of the types \( X \) and \( Y \), denoted by \( X \times Y \).

At first glance, it might seem odd that a sum is also a product, but exactly the same thing happens with numbers, for the sum \( 5 + 5 + 5 \) is also referred to as the product \( 3 \times 5 \). Indeed, that’s one way to define \( 3 \times 5 \).

Recall that we have seen something similar with the product type \( \prod_{x : X} Y(x) \), which we let \( X \to Z \) denote in the case where \( Y(x) \) is a constant family of the form \( Y(x) \equiv Z \), for some type \( Z \).

The type \( X \times Y \) inherits the functions \( \text{fst} \) and \( \text{snd} \) from \( \sum_{x : X} Y(x) \), with the same definitions \( \text{fst}(x, y) \equiv x \) and \( \text{snd}(x, y) \equiv y \). Their types can now be denoted in a simpler way as \( \text{fst} : (X \times Y) \to X \) and \( \text{snd} : (X \times Y) \to Y \), and they are called as before the first and the second projection, respectively.

Again, proving something about (or constructing something from) every element \((a, b)\) of \( X \times Y \) is simply done for all \( a : X \) and \( b : Y \).

There is an equivalence between \((a_1, b_1) \equiv (a_2, b_2)\) and \((a_1 \equiv a_2) \times (b_1 \equiv b_2)\). This follows from Lemma 2.10.3 together with Exercise 2.5.6.
If \( f : X \to Y \) and \( f' : X' \to Y' \), then we let \( f \times f' \) denote the map of type \((X \times X') \to (Y \times Y')\) that sends \((x, x')\) to \((f(x), f'(x'))\).

The following lemma follows from Lemma \ref{lem:isEq-pair-bin}, combined with Definition \ref{def:isEq-pair-bin} and Exercise \ref{exe:isEq-pair-bin}.

**Lemma 2.11.1.** Suppose we are given type \( X \) and \( Y \). For any elements \((x, y)\) and \((x', y')\) of \( X \times Y \), the map defined in Definition \ref{def:isEq-pair-bin} defined by

\[
(p, q) \mapsto (p, q)
\]

is an equivalence of type

\[
(x \not\equiv x') \times (y \not\equiv y') \not\equiv ((x, y) \not\equiv (x', y')).
\]

**Exercise 2.11.2.** Let \( X, Y \) be types in a universe \( \mathcal{U} \), and consider the type family \( T(z) \) in \( \mathcal{U} \) depending on \( z : \text{Bool} \) defined by \( T(\text{no}) \equiv X \) and \( T(\text{yes}) \equiv Y \). Show that the function \((\prod_{b : \text{Bool}} T(b)) \to X \times Y\) sending \( f \) to \((f(\text{no}), f(\text{yes}))\), is an equivalence.

**Exercise 2.11.3.** Let \( X \) and \( Y \) be types. Construct an equivalence of type \((X \times Y) \not\equiv (Y \times X)\).

\section*{2.12 More inductive types}

There are other examples of types that are conveniently introduced in the same way as we have seen with the natural numbers and the identity types. A type presented in this style shares some common features: there are some ways to create new elements, and there is a way (called \textit{induction}) to prove something about every element of the type (or family of types). We will refer to such types as \textit{inductive} types, and we present a few more of them in this section, including the finite types, and then we present some other constructions for making new types from old ones. For each of these constructions we explain the identity type for two elements of the newly constructed type in terms of identity types for elements of the constituent types.

\subsection*{2.12.1 Finite types}

Firstly, there is the \textit{empty} type in the universe \( \mathcal{U}_0 \), denoted by \( \emptyset \) or by False. It is an inductive type, with no way to construct elements of it. The induction principle for \( \emptyset \) says that to prove something about (or to construct something from) every element of \( \emptyset \), it suffices to consider no special cases (!). Hence, every statement about an arbitrary element of \( \emptyset \) can be proven. (This logical principle is traditionally called \textit{ex falso sequitur quodlibet}.)\footnote{From falsehood, anything follows. Also called the principle of explosion.} As an example, we may prove that any two elements \( x \) and \( y \) of \( \emptyset \) are equal (i.e., construct an identification of type \( x \not\equiv y \)) by using induction on \( x \). We may even prove by induction on \( x : \emptyset \) that the elements 0 and succ(0) of \( \mathbb{N} \) are equal (i.e., construct a function of type \( \emptyset \to (0 \not\equiv \text{succ(0)}) \)).

An element of \( \emptyset \) will be called an \textit{absurdity}. Of course, one expects that there are no real absurdities in mathematics, nor in any logical system (such as ours) that attempts to provide a language for mathematics, but it is important to have such a name so we can discuss the possibility, which might result inadvertently from the introduction of unwarranted
assumptions. For example, to assert that a type $T$ has no elements, it would be sensible to assert that an element of $T$ would lead to an absurdity. Providing a function of type $T \to \emptyset$ is a convenient way to make that assertion.

Secondly, there will also be an inductive type called True in the universe $\mathbb{U}_0$ provided with a single element $\text{triv}$; (the name $\text{triv}$ comes from the word “trivial”). Its induction principle states that, in order to prove something about (or to construct something from) every element of True, it suffices to consider the special case where the element is $\text{triv}$. As an example, we may construct, for any element $u : \text{True}$, an identification of type $u \xrightarrow{\mathbin{\sim}} \text{triv}$; we use induction to reduce to the case where $u$ is $\text{triv}$, and then $\text{refl}_{\text{triv}}$ provides the desired element. One may also construct, for any elements $x$ and $y$ of True, an identification of type $x \xrightarrow{\mathbin{\sim}} y$ by using induction both on $x$ and on $y$.

There is a function $X \to \text{True}$, for any type $X$, namely: $a \mapsto \text{triv}$. This corresponds, for propositions, to the statement that an implication holds if the conclusion is true.

Exercise 2.12.2. Let $X$ be a type. Define the function $e$ of type $(\text{True} \to X) \to X$ by $e(f) \equiv f(\text{triv})$. Prove that $e$ is an equivalence. This is called the universal property of True.

Thirdly, there will be an inductive type called Bool in the universe $\mathbb{U}_0$, provided with two elements, yes and no. Its induction principle states that, in order to prove something about (or to construct something from) every element of Bool, it suffices to consider two cases: the special case where the element is yes and the special case where the element is no.

We may use substitution to construct an element of type $(\text{yes} \xrightarrow{\mathbin{\sim}} \text{no}) \to \emptyset$, expressing that the identification of yes with no leads to an absurdity. To do this, we introduce a family of types $P(b)$ in the universe $\mathbb{U}_0$ parametrized by a variable $b : \text{Bool}$. We define $P(b)$ by induction on $b$ by setting $P(\text{yes}) \equiv \text{True}$ and $P(\text{no}) \equiv \text{False}$. (The definition of $P(b)$ is motivated by the expectation that we will be able to construct an equivalence between $P(b)$ and $\text{yes} \xrightarrow{\mathbin{\sim}} b$.) If there were an element $e : \text{yes} \xrightarrow{\mathbin{\sim}} \text{no}$, we could substitute no for yes in $\text{triv} : P(\text{yes})$ to get an element of $P(\text{no})$, which is absurd. Since $e$ was arbitrary, we have defined a function $(\text{yes} \xrightarrow{\mathbin{\sim}} \text{no}) \to \emptyset$, as desired.

In the same way, we may use substitution to prove that it is absurd that successors of natural numbers are identical to 0, i.e., for any $n : \mathbb{N}$ that $(0 \xrightarrow{\mathbin{\sim}} \text{succ}(n)) \to \emptyset$. To do this, we introduce a family of types $P(i)$ in $\mathbb{U}_0$ parametrized by a variable $i : \mathbb{N}$. Define $P$ recursively by specifying that $P(0) \equiv \text{True}$ and $P(\text{succ}(m)) \equiv \text{False}$. (The definition of $P(i)$ is motivated by the expectation that we will be able to construct an equivalence between $P(i)$ and $0 \xrightarrow{\mathbin{\sim}} i$.) If there were an element $e : 0 \xrightarrow{\mathbin{\sim}} \text{succ}(n)$, we could substitute $\text{succ}(n)$ for 0 in $\text{triv} : P(0)$ to get an element of $P(\text{succ}(n))$, which is absurd. Since $e$ was arbitrary, we have defined a function $(0 \xrightarrow{\mathbin{\sim}} \text{succ}(n)) \to \emptyset$, establishing the claim.

In a similar way we will in Section 2.24 define types $n$ for any $n$ in $\mathbb{N}$ such that $n$ is a type (set) of $n$ elements.
2.12.3 Binary sums

For sum types of the form $\sum_b : \text{Bool} \; T(b)$, with $T(b)$ a type depending on $b$ in Bool, there is an equivalence with a simpler type.37 After all, the type family $T(b)$ is fully determined by two types, namely by the types $T(\text{no})$ and $T(\text{yes})$. The elements of $\sum_b : \text{Bool} \; T(b)$ are dependent pairs $(\text{no}, x)$ with $x$ in $T(\text{no})$ and $(\text{yes}, y)$ with $y$ in $T(\text{yes})$. The resulting type can be viewed as the disjoint union of $T(\text{no})$ and $T(\text{yes})$: from an element of $T(\text{no})$ or an element of $T(\text{yes})$ we can produce an element of $\sum_b : \text{Bool} \; T(b)$.

These disjoint union types can be described more clearly in the following way. The binary sum of two types $X$ and $Y$, denoted $X \sqcup Y$, is an inductive type with two constructors: $\text{inl} : X \to X \sqcup Y$ and $\text{inr} : Y \to X \sqcup Y$.38 Proving a property of any element of $X \sqcup Y$ means proving that this property holds of any $\text{inl}_x$ with $x : X$ and any $\text{inr}_y$ with $y : Y$. In general, constructing a function $f$ of type $\prod z : X \sqcup Y \; T(z)$, where $T(z)$ is a type depending on $z$, is done by defining $f(\text{inl}_x)$ for all $x$ in $X$ and $f(\text{inr}_y)$ for all $y$ in $Y$.

Exercise 2.12.4. Let $X$, $Y$ be types in a universe $\mathcal{U}$, and consider the type family $T(z)$ in $\mathcal{U}$ depending on $z : \text{Bool}$ defined by induction on $z$ by $T(\text{no}) \equiv X$ and $T(\text{yes}) \equiv Y$. Show that the map $f : X \sqcup Y \to \sum_b : \text{Bool} \; T(b)$, defined by $f(\text{inl}_x) \equiv (\text{no}, x)$ and $f(\text{inr}_y) \equiv (\text{yes}, y)$, is an equivalence.

Identification of two elements $a$ and $b$ in $X \sqcup Y$ is only possible if they are constructed with the same constructor. Thus $\text{inl}_x \to \text{inr}_y$ is always empty, and there are equivalences of type $(\text{inl}_x \to \text{inl}_x') \to (x \to x')$ and $(\text{inr}_y \to \text{inr}_y') \to (y \to y')$.

Exercise 2.12.5. Prove these statements using Exercise 2.12.4, Lemma 2.10.3, and a characterization of the identity types of Bool.

Exercise 2.12.6. Let $X$, $Y$, $Z$ be types. Define a function $e$ from $(X \sqcup Y) \to Z$ to $(X \to Z) \times (Y \to Z)$ by precomposition with the constructors. Prove that $e$ is an equivalence. This is called the universal property of the binary sum.

Exercise 2.12.7. Let $X$ be a type. Construct an equivalence of type $(X \sqcup \emptyset) \to X$.

2.12.8 Unary sums

Sometimes it is useful to be able to make a copy of a type $X$: A new type that behaves just like $X$, though it is not equal to $X$ by definition. The unary sum or wrapped copy of $X$ is an inductive type $\text{Copy}(X)$ with a single constructor, $\text{in} : X \to \text{Copy}(X)$.39 Constructing a function $f : \prod z : \text{Copy}(X) \; T(z)$, where $T(z)$ is a type depending on $z : \text{Copy}(X)$, is done by defining $f(\text{in}_x)$ for all $x : X$. Taking $T(z)$ to be the constant family at $X$, we get a function, out : $\text{Copy}(X) \to X$, called the destructor, with $\text{out}(\text{in}_x) \equiv x$ for $x : X$, and the induction principle implies that $\text{in}_x \to z$ for all $z : \text{Copy}(X)$, so there is an equivalence of type $\text{Copy}(X) \to X$, as expected. It follows that there are equivalences of type $(\text{in}_x \to \text{in}_x') \to (x \to x')$ and $(\text{out}(z) \to \text{out}(z')) \to (z \to z')$.

Note that we can make several copies of $X$ that are not equal to each other by definition, for instance, by picking different names for the

37 In a case like this, we can thicken up the lines denoting $T(\text{no})$ and $T(\text{yes})$ in our picture, if we like:

```
\begin{diagram}
\text{inr} & \text{no} \\
\text{inl} & \text{yes} \\
\end{diagram}
```

38 Be aware that in a picture, the same point may refer either to $x$ in $X$ or to $\text{inl}_x$ in the sum $X \sqcup Y$:

```
\begin{diagram}
X & Y \\
\text{inl} & \text{inr} \\
\end{diagram}
```

39 A point $x : X$ corresponds to the point $\text{in}_x : \text{Copy}(X)$:

```
\begin{diagram}
X & \text{in}_x \\
\text{in} & \end{diagram}
```

Note that $\text{Copy}(X)$ can alternatively be defined as $\sum_z : \text{True} \; X$. 
The univalence axiom, to be presented in this section, greatly enhances our ability to produce identifications between the two types and to use the resulting identifications to transport (in the sense of Definition 2.5.4) properties and structure between the types. It asserts that if \( \mathcal{U} \) is a universe, and \( X \) and \( Y \) are types in \( \mathcal{U} \), then a specific function, mapping identifications between \( X \) and \( Y \) to equivalences between \( X \) and \( Y \), is an equivalence.

We now define the function that the univalence axiom postulates to be an equivalence.

**Definition 2.13.1.** For types \( X \) and \( Y \) in a universe \( \mathcal{U} \) and a path \( p : X \to Y \), transport along \( p \) in the type family \( \text{id}_{\mathcal{U}} \) is a function from \( X \) to \( Y \). We recall the definition by path induction from Definition 2.5.4, setting \( \text{trp}^{\text{id}_{\mathcal{U}}} \equiv \text{id}_{X} \). As observed in Section 2.9, transport functions are equivalences, so that the result is a function

\[
(p \mapsto \text{trp}^{\text{id}_{\mathcal{U}}}(p) : (X \to Y) \to (X \to Y)).
\]

We may write \( \text{trp}^{\text{id}_{\mathcal{U}}} \) more briefly as \( \bar{p} \), which we also use to denote the corresponding function of type \( X \to Y \), instead of \( X \to Y \).

We are ready to state the univalence axiom.

**Principle 2.13.2 (Univalence Axiom).** Let \( \mathcal{U} \) be a universe. Voevodsky’s univalence axiom for \( \mathcal{U} \) postulates that \( p \mapsto \bar{p} \) is an equivalence of type \( (X \to Y) \to (X \to Y) \), for all \( X, Y : \mathcal{U} \). Formally, we postulate the existence of a family of elements

\[
u_{X,Y} : \text{isEquiv}(p : X \to Y) \mapsto \text{trp}^{\text{id}_{\mathcal{U}}}(p)
\]

parameterized by \( X, Y : \mathcal{U} \).

For an equivalence \( f : X \to Y \), we will adopt the notation \( \bar{f} : X \to Y \) to denote \( (p \mapsto \bar{p})^{-1}(f) \), the result of applying the inverse function of \( p \mapsto \bar{p} \), given by \( \nu_{X,Y} \), to \( f \). Thus there are identifications of type \( \bar{p} \to p \) and \( \bar{f} \to f \). There are also identifications of type \( \bar{id}_X \to \text{refl}_X \) and \( \bar{g} \bar{f} \to \bar{g} \bar{f} \) if \( g : Y \to Z \).

---

4 We implement this in Definition 3.2.1.
Exercise 2.13.3. Prove that \( \mathbb{B} \xrightarrow{\text{refl}} \mathbb{B} \) has exactly two elements, \( \text{refl}_{\mathbb{B}} \) and \( \text{twist} \) (where \( \text{twist} \) is given by univalence from the equivalence \( \mathbb{B} \xrightarrow{\text{refl}} \mathbb{B} \) interchanging the two elements of \( \mathbb{B} \)), and that \( \text{twist} \cdot \text{twist} \xrightarrow{\text{refl}} \text{refl}_{\mathbb{B}} \).

\[\]

2.14 Heavy transport

In this section we collect useful results on transport in type families that are defined by a type constructor applied to families of types. Typical examples of such ‘structured’ type families are \( Y(x) \xrightarrow{} Z(x) \) and \( x \xrightarrow{} x \) parametrized by \( x : X \).

Definition 2.14.1. Let \( X \) be a type, and let \( Y(x) \) and \( Z(x) \) be families of types parametrized by a variable \( x : X \). Define \( Y \to Z \) to be the type family with \( (Y \to Z)(x) \equiv Y(x) \to Z(x) \).

Recall from Definition 2.9.13 that an element \( f : \prod_{x : X} (Y \to Z)(x) \) is called a fiberwise map, and \( f \) is called a fiberwise equivalence, if \( f(x) : Y(x) \to Z(x) \) is an equivalence for all \( x : X \).

Construction 2.14.2. Let \( X \) be a type, and let \( Y(x) \) and \( Z(x) \) be types for every \( x : X \). Then we have for every \( x, x' : X, e : x \xrightarrow{} x', f : Y(x) \to Z(x) \), and \( y' : Y(x') \) (see the diagram in the margin):

\[ \text{trp}^\text{Y \to Z}(f)(y') \xrightarrow{\text{equiv}} \text{trp}^ \text{Z}( f( \text{trp}^\text{Y}(y')) ) . \]

Implementation of Construction 2.14.2. By induction on \( e : x \xrightarrow{} x' \). For \( e \equiv \text{refl}_x \), we have \( e^{-1} \equiv \text{refl}_x \), and all transports are identity functions of appropriate type.

An important special case of the above lemma is with \( \mathcal{U} \) as parameter type and type families \( Y : Z \equiv \mathbf{id}_\mathcal{U} \). Then \( Y \to Z \) is \( X \mapsto (X \to X) \). Now, if \( A, B : \mathcal{U} \) and \( e : A \xrightarrow{} B \) comes from an equivalence \( g : A \xrightarrow{} B \) by applying the univalence axiom, then the above construction combined with function extensionality yields that for any \( f : A \to A \) (see the diagram in the margin)

\[ \text{trp}^\text{Y \to X}(f) \xrightarrow{\text{equiv}} g \circ f \circ g^{-1} . \]

The following construction is implemented by induction on \( e : x \xrightarrow{} x' \).

Construction 2.14.3. Let \( X, Y \) be types, \( f, g : X \to Y \) functions, and let \( Z(x) \equiv (f(x) \xrightarrow{} g(x)) \) for every \( x : X \). Then for all \( x, x' \) in \( X \), \( e : x \xrightarrow{} x' \), and \( i : f(x) \xrightarrow{} g(x) \) we have:

\[ \text{trp}^\text{Z}(i) \xrightarrow{\text{equiv}} \text{ap}_g(e) \cdot i \cdot \text{ap}_f(e)^{-1} . \]

Exercise 2.14.4. Implement Construction 2.14.3 in the following special cases, where \( Y \equiv X \) and \( a, b \) are elements of \( X \):

1. \( \text{trp}_e^{a \xrightarrow{} b}(i) \xrightarrow{\text{equiv}} i \);
2. \( \text{trp}_e^{a \xrightarrow{} a}(i) \xrightarrow{\text{equiv}} e \cdot i \);
3. \( \text{trp}_e^{a \xrightarrow{} b}(i) \xrightarrow{\text{equiv}} i \cdot e^{-1} \);
4. \( \text{trp}_e^{a \xrightarrow{} a}(i) \xrightarrow{\text{equiv}} e \cdot i \cdot e^{-1} \) (also called conjugation).

\[\]
There is also a dependent version of Construction 2.14.3, which is again proved by induction on $e$.

**CONSTRUCTION 2.14.5.** Let $X, Y(x)$ be types and $f(x), g(x) : Y(x)$ for all $x : X$. Let $Z(x) \equiv (f(x) \xrightarrow{e} g(x))$, with the identification in $Y(x)$, for every $x : X$. Then for all $x, x' \in X$, $e : x \xrightarrow{e} x'$, and $i : f(x) \xrightarrow{e} g(x)$ we have:

\[
\text{trp}^Z_i(i) \xrightarrow{e} \text{po}_e(\text{apd}_i(e)) \cdot \text{apd}_i(i) : \text{po}_e(\text{apd}_i(e))^{-1}.
\]

The following construction will be used later in the book.

**DEFINITION 2.14.6.** Let $X, Y(x)$ be types and $f(x) : Y(x)$ for all $x : X$. Given elements $x, x' : X$ and a path $p : x \xrightarrow{e} x'$, we define an equivalence $(f(x) \xrightarrow{e} f(x')) \xrightarrow{e} (f(x) \xrightarrow{e} f(x))$. We do this by induction on $p$, using Definition 2.7.1, thereby reducing to the case $(f(x) \xrightarrow{e} f(x)) \xrightarrow{e} (f(x) \xrightarrow{e} f(x))$, which we solve in the canonical way as before.

## 2.15 Propositions, sets and groupoids

Let $P$ be a type. The property that $P$ has at most one element may be expressed by saying that any two elements are equal. Hence it is encoded by $\prod_{a,b : P}(a \sim b)$. We shall call a type $P$ with that property a *proposition*, and its elements will be called *proofs* of $P$. We will use them for doing logic in type theory. The reason for doing so is that the most relevant thing about a logical proposition is whether it has a proof or not. It is therefore reasonable to require for any type representing a logical proposition that all its members are equal.

Suppose $P$ is a proposition. Then English phrases such as “$P$ holds”, “we know $P$”, and “we have shown $P$”, will all mean that we have an element of $P$. We will not use such phrases for types that are not propositions, nor will we discuss knowing $P$ conditionally with a phrase such as “whether $P$”. Similarly, if “$Q$” is the English phrase for a statement encoded by the proposition $P$, then the English phrases “$Q$ holds”, “we know $Q$”, and “we have shown $Q$”, will all mean that we have an element of $P$.

Typically, mathematical properties expressed in English as *adjectives* will be encoded by types that are propositions, for in English speech, when you assert that a certain adjective holds, you are simply asserting it, and not providing further information. Examples: the number 6 is *even*; the number 7 is *prime*; the number 28 is *perfect*; consider a *regular* pentagon; consider an *isosceles* triangle.

Sometimes adjectives are used in mathematics, not to refer to properties of an object, but to modify the meaning of a noun, producing a different noun phrase denoting a different mathematical concept. For example, a *directed* graph is a graph, each of whose edges is given a bit of additional information: a direction in which it points. Other examples: *differentiable* manifold; *bipartite* graph; *vector* space; *oriented* manifold.

Let $X$ be a type. If for any $x : X$ and any $y : X$ the identity type $x \xrightarrow{e} y$ is a proposition, then we shall say that $X$ is a *set*. The reason for doing so is that the most relevant thing about a set is which elements it has; distinct identifications of equal elements are not relevant. Alternatively, we shall say that $X$ is a *0-type*.

---

Footnotes:

41 Sets are thought to consist of points. Points are entities of dimension 0, which explains why the count starts here. One of the contributions of Vladimir Voevodsky is the extension of the hierarchy downwards, with the notion of proposition, including logic in the same hierarchy. Some authors therefore call propositions $(-1)$-types, and they call contractible types $(-2)$-types.
The following definition introduces notational alternatives commonly used in mathematics.

**Definition 2.15.1.** Let \( P \) be a proposition as defined above. We define the *negation* of \( P \) by setting \( \neg P \iff (P \rightarrow \emptyset) \).

Let \( A \) be a set, as defined above, and let \( a \) and \( b \) be elements of \( A \). We write \( a = b \) as alternative notation for the type \( a \rightarrow b \). Formally, we define it as follows.

\[
(a = b) \iff (a \rightarrow b)
\]

The type \( a = b \) is called an *equation*. When it has an element, we say that \( a \) and \( b \) are *equal*. In line with this definition we also define the type \( (a \neq b) \iff \neg(a = b) \); an element of it asserts that the elements \( a \) and \( b \) of the set \( A \) are not equal.

Equations are propositions, so we can speak of them being true or false, and we may use them after the words *if, since, whether, and because* in a sentence. In set theory, everything is a set and all equations \( a = b \) are propositions; our definition of \( a = b \) is designed to make the transition from set theory to type theory minimally disconcerting.

(Good motivation for the form of the equal sign in the notation \( a = b \) is provided by a remark made by Robert Recorde in 1557 in the *Whetstone of Witte*\(^3\): “And to avoid the tedious repetition of these words is equal to, I will set, as I do often in work use, a pair of parallels, or twin lines of one length, thus: =, because no two things can be more equal.”\(^4\) In fact, the remark of Recorde presages the approach described in this book, for although those two little lines are congruent, they were not considered to be equal traditionally, since they are in different places, whereas they may be considered to be equal in the presence of univalence, which converts congruences to identifications.)

Let \( X \) be a type. If for any \( x : X \) and any \( y : X \) the identity type \( x \rightarrow y \) is a set, then we shall say that \( X \) is a *groupoid*, also called a 1-type.

The pattern continues. If for any \( n : \mathbb{N} \), any \( x : X \), and any \( y : X \) the identity type \( x \rightarrow y \) is an \( n \)-type, then we shall say that \( X \) is an \((n+1)\)-type.

If \( X \) is an \( n \)-type, we also say that \( X \) is *\( n \)-truncated*.

We prove that every proposition is a set, from which it follows by induction that every \( n \)-type is an \((n+1)\)-type.

**Lemma 2.15.2.** Every type that is a proposition is also a set.

**Proof.** Let \( X \) be a type and let \( f : \prod_{a,b:X}(a \rightarrow b) \). Let \( a, b, c : X \) and let \( P(x) \) be the type \( a \rightarrow x \) depending on \( x : X \). Then \( f(a, b) : P(b) \) and \( f(a, c) : P(c) \). By path induction we construct for all \( q : b \rightarrow c \) an identification of type \( q : f(a, b) \rightarrow f(a, c) \). For this it suffices to observe that \( \text{refl}_b \cdot f(a, b) \) and \( f(a, b) \) are equal by definition. Since \( a \) is arbitrary, it follows that any \( q : b \rightarrow c \) can be identified with \( f(b, c) \cdot f(b, b)^{-1} \), which doesn't depend on \( q \). Hence \( X \) is a set.

A more interesting example of a set is \( \text{Bool} \).

**Lemma 2.15.3.** \( \text{Bool} \) is a set.

**Proof.** The following elegant, self-contained proof is due to Simon Huber. For proving \( \rightarrow q \) for all \( b, b' : \text{Bool} \) and \( p, q : b \rightarrow b' \), it suffices (by induction on \( q \)) to show \( p \rightarrow \text{refl}_b \) for all \( b : \text{Bool} \) and \( p : b \rightarrow b \). To this end, define by induction on \( b, b' \): \( \text{Bool} \), a type \( C(b, b', p) \) for all \( p : b \rightarrow b' \),

---

\(^3\)Robert Recorde and John Kingston. *The whetstone of Witte: whiche is the seconde parte of Arithmetike, containing the extraction of rootes, the cosseike practise, with the rule of equation, and the workes of surde numbers*. Imprinted at London: By Ihon Kyngestone, 1557. URL: https://archive.org/details/TheWhetstoneOfWitte.

\(^4\)And to auoide the tediouse repetition of these worde: if equalle to: I will sette of these worde, a paire of paralleles, or Gemowe lines of one lengthe, thus: ——, because noe two, line, can be moare equalle.
by setting $C(\text{yes, yes, } p) \equiv (p \to \text{refl}_\text{yes})$, $C(\text{no, no, } p) \equiv (p \to \text{refl}_\text{no})$, and arbitrary in the other two cases. By induction on $b$ one proves that $C(b, b, p) \to (p \to \text{refl}_b)$ for all $p$. Hence it suffices to prove $C(b, b', p)$ for all $b, b' : \text{Bool}$ and $p : b \to b'$. By induction on $p$ this reduces to $C(b, b, \text{refl}_b)$, which is immediate by induction on $b : \text{Bool}$. □

We now collect a number of useful results on propositions.

**Lemma 2.15.4.** Let $A$ be a type, and let $P$ and $Q$ propositions. Let $R(a)$ be a proposition depending on $a : A$. Then we have:

1. False and True are propositions;
2. $A \to P$ is a proposition;
3. $\prod_{a : A} R(a)$ is a proposition;
4. $P \times Q$ is a proposition;
5. If $A$ is a proposition, then $\sum_{a : A} R(a)$ is a proposition;
6. $P \perp P$ is a proposition.

**Proof.** (1): If $p, q : \text{False}$, then $p \to q$ holds by induction for False. If $p, q : \text{True}$, then $p \to q$ is proved by double induction, which reduces the proof to observing that $\text{refl}_\text{triv} : \text{triv} \to \text{triv}$.

(2): If $p, q : A \to P$, then $p \to q$ is proved by first observing that $p$ and $q$ are functions which, by function extensionality, can be identified if they have equal values $p(x) = q(x)$ in $P$ for all $x$ in $A$. This is actually the case since $P$ is a proposition.

(3): If $p, q : \prod_{a : A} R(a)$ one can use the same argument as for $A \to P$ but now with dependent functions $p, q$.

(4): If $(p_1, q_1), (p_2, q_2) : P \times Q$, then $(p_1, q_1) \to (p_2, q_2)$ is proved componentwise. Alternatively, we may regard this case as a special case of (5).

(5): Given $(a_1, r_1), (a_2, r_2) : \sum_{a : A} R(a)$, we must establish that $(a_1, r_1) \to (a_2, r_2).$ Combining the map in Definition 2.10.1 with the identity type in Definition 2.7.3 yields a map $((a_1, r_1) \to (a_2, r_2))$, so it suffices to construct an element in the source of the map. Since $A$ is a proposition, we may find $u : a_1 = a_2$. Since $R(a_1)$ is a proposition, we may find $v : \text{trp}_a^Y(r_1) = r_2$. The pair $(u, v)$ is what we wanted to find.

(6): If $p, q : P \perp \neg P$, then we can distinguish four cases based on $\text{inl}/\text{inr}$, see Section 2.8. (6): If $p, q : P \perp \neg P$, then we can distinguish four cases based on $\text{inl}/\text{inr}$, see Section 2.8. In two cases we have both $P$ and $\neg P$ and we are done. In the other two, either $p \equiv \text{inl}_P$ and $q \equiv \text{inl}_{\neg P}$ with $p', q' : P$, or $p \equiv \text{inr}_{\neg P}$ and $q \equiv \text{inr}_P$ with $p', q' : \neg P$. In both these cases we are done since $P$ and $\neg P$ are propositions.

Several remarks can be made here. First, the lemma supports the use of False and True as truth values, and the use of $\to, \prod \times$ for implication, universal quantification, and conjunction, respectively. Since False is a proposition, it follows by (2) above that $A \to \emptyset$ is a proposition for any type $A$. As noted before, (2) is a special case of (3).

Notably absent in the lemma above are disjunction and existential quantification. This has a simple reason: True $\perp$ True has two distinct elements $\text{inl}_{\text{triv}}$ and $\text{inr}_{\text{triv}}$, an is therefore not a proposition. Similarly, $\sum_{a : A} \text{True}$ has infinitely many distinct elements $(n, \text{triv})$ and is not a
an introduction to univalent mathematics

proposition. We will explain in Section 2.16 how to work with disjunction and existential quantification for propositions.

The lemma above has a generalization from propositions to \( n \)-types which we state without proving. (The proof goes by induction on \( n \), with the lemma above serving as the base case where \( n = -1 \).)

**Lemma 2.15.5.** Let \( A \) be a type, and let \( X \) and \( Y \) be \( n \)-types. Let \( Z(a) \) be an \( n \)-type depending on \( a : A \). Then we have:

1. \( A \rightarrow X \) is an \( n \)-type;
2. \( \prod_{a : A} Z(a) \) is an \( n \)-type;
3. \( X \times Y \) is an \( n \)-type.
4. If \( A \) is an \( n \)-type, then \( \sum_{a : A} Z(a) \) is an \( n \)-type;

We formalize the definitions from the start of this section.

**Definition 2.15.6.**

\[
\begin{align*}
\text{isProp}(P) & \equiv \prod_{p, q : P} (p \rightarrow q) \\
\text{isSet}(S) & \equiv \prod_{x, y : S} \text{isProp}(x \rightarrow y) \equiv \prod_{x, y : S} \prod_{p, q : \text{trp}(x \rightarrow y)} (p \rightarrow q) \\
\text{isGrpd}(G) & \equiv \prod_{g, h : G} \text{isSet}(g \rightarrow h) \equiv \ldots
\end{align*}
\]

**Lemma 2.15.7.** For any type \( A \), the following types are propositions:

1. \( \text{isContr}(A) \);
2. \( \text{isProp}(A) \);
3. \( \text{isSet}(A) \);
4. \( \text{isGrpd}(A) \);
5. the type that encodes whether \( A \) is an \( n \)-type, for \( n \geq 0 \).

Consistent with that, we will use identifiers starting with “is” only for names of types that are propositions. Examples are \( \text{isSet}(A) \) and \( \text{isGrpd}(A) \), and also \( \text{isEquiv}(f) \).

**Proof.** Recall that \( \text{isContr}(A) \) is \( \sum_{a : A} \prod_{y : A} (a \rightarrow y) \). Let \( (a, f) \) and \( (b, g) \) be elements of the type \( \text{isContr}(A) \). By Definition 2.10.1, to give an element of \( (a, f) \rightarrow (b, g) \) it suffices to give an \( e : a \rightarrow b \) and an \( e' : f \rightarrow g \). For \( e \) we can take \( f(b) \); for \( e' \) it suffices by Definition 2.7.3 to give an \( e'' : \text{trp}_e f \rightarrow g \). Clearly, \( A \) is a proposition and hence a set by Lemma 2.15.2. Hence the type of \( g \) is a proposition by Lemma 2.15.4(3), which gives us \( e'' \).

We leave the other cases as exercises. \( \square \)

**Exercise 2.15.8.** Make sure you understand that \( \text{isProp}(P) \) is a proposition, using the same lemmas as for \( \text{isContr}(A) \). Show that \( \text{isSet}(S) \), \( \text{isGrpd}(G) \) and \( \text{isEquiv}(f) \) are propositions. \( \downarrow \)

The following exercise shows that the inductive definition of \( n \)-types can indeed start with \( n \) as \( -2 \), where we have the contractible types.

**Exercise 2.15.9.** Given a type \( P \), show that \( P \) is a proposition if and only if \( p \rightarrow q \) is contractible, for any \( p, q : P \). \( \downarrow \)
Remark 2.15.10. We now present the notion of a diagram. A diagram is a graph whose vertices are types and whose edges are functions. Here is an example.

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow{p} & & \downarrow{q} \\
S & \xrightarrow{g} & T
\end{array}
\]

The information conveyed by this diagram to the reader is that \(X, Y, S,\) and \(T\) are types, and that \(f, g, p,\) and \(q\) are functions; moreover, \(f\) is of type \(X \to Y,\) \(g\) is of type \(S \to T,\) \(p\) is of type \(X \to S,\) and \(q\) is of type \(Y \to T.\)

Observe that we can travel through the diagram from \(X\) to \(T\) by following first the arrow labeled \(f\) and then the arrow labelled \(q.\) Consequently, the composite function \(q \circ f\) is of type \(X \to T.\)

There is another route from \(X\) to \(T:\) we could follow first the arrow labeled \(p\) and then the arrow labelled \(g.\) Consequently, the composite function \(g \circ p\) is also of type \(X \to T.\)

We say that a diagram is commutative by definition if, whenever there are two routes from one vertex to another, the corresponding composite functions are equal by definition. For example, in the diagram above, the condition would be that \(g \circ p = q \circ f.\)

When the function type from any vertex of a diagram to any other vertex of the diagram is a set, then equality of functions is a proposition, and we may consider whether two functions are equal. In that case, we say that a diagram is commutative if, whenever there are two routes from one vertex to another, the corresponding composite functions are equal. For example, in the diagram above, the condition would be that \(g \circ p = q \circ f.\)

In general, a diagram is a visual way to represent identity types. For example, if in the above diagram the type \(X \to T\) is not a set, then the diagram represents the identity type \(g \circ p \simeq q \circ f.\)

There are other sorts of diagrams. For example, identifications may be composed, and thus we may have a diagram of identifications between elements of the same type. For example, suppose \(W\) is a type, suppose that \(x, y, s,\) and \(t\) are elements of \(W,\) and consider the following diagram.

\[
\begin{array}{ccc}
x & \xrightarrow{f} & y \\
\downarrow{p} & & \downarrow{q} \\
s & \xrightarrow{g} & t
\end{array}
\]

It indicates that \(f\) is of type \(x \xrightarrow{\sim} y,\) \(g\) is of type \(s \xrightarrow{\sim} t,\) \(p\) is of type \(x \xrightarrow{\sim} s,\) and \(q\) is of type \(y \xrightarrow{\sim} t.\) We may also consider whether such a diagram is commutative by definition, or, in the case where all the identity types are sets, is commutative. Such diagrams are again a visual way to represent identity types. 45For example, the above diagram represents the identity type \(g \circ p \xrightarrow{\sim} q \circ f.\) For a concrete example, see the naturality square in Definition 2.6.5.
2.16 Propositional truncation and logic

As explained in Section 2.15, the type formers $\to$, $\prod$, $\times$ can be used with types that are propositions for the logical operations of implication, universal quantification, and conjunction, respectively. Moreover, True and False can be used as truth values, and $\neg$ can be used for negation. We have also seen that $\sqcup$ and $\Sigma$ can lead to types that are not propositions, even though the constituents are propositions. This means we are still lacking disjunction ($P \lor Q$) and existence ($\exists_{x : X} P(x)$) from the standard repertoire of logic, as well as the notion of non-emptiness of a type. In this section we explain how to implement these three notions.

To motivate the construction that follows, consider non-emptiness of a type $T$. In order to be in a position to encode the mathematical assertion expressed by the English phrase “$T$ is non-empty”, we will need a proposition $P$. The proposition $P$ will have to be constructed somehow from $T$. Any element of $T$ should somehow give rise to an element of $P$, but, since all elements of propositions are equal to each other, all elements of $P$ arising from elements of $T$ should somehow be made to equal each other. Finally, any proposition $Q$ that is a consequence of having an element of $T$ should also be a consequence of $P$.

We define now an operation called propositional truncation,\textsuperscript{46} that enforces that all elements of a type become equal.

**Definition 2.16.1.** Let $T$ be a type. The propositional truncation of $T$ is the type $\|T\|$ defined by the following constructors:

1. an element constructor $\|t\| : \|T\|$ for all $t : T$;
2. an identification constructor providing an identification of type $x \sim y$ for all $x, y : \|T\|$.

The identification constructor ensures that $\|T\|$ is a proposition. The induction principle states that, for any family of propositions $P(x)$ parametrized by a variable $x : \|T\|$, in order to prove $\prod_{x : \|T\|} P(x)$, it suffices to prove $\prod_{t : T} P(\|t\|)$. In other words, in order to define a function $f : \prod_{x : \|T\|} P(x)$, it suffices to give a function $g : \prod_{t : T} P(\|t\|)$. Moreover, the function $f$ will satisfy $f(\|t\|) \equiv g(t)$ for all $t : T$.

Consider the special case where the family $P(x)$ is constant. We see that any function $g : T \to P$ to a proposition $P$ yields a (unique) function $f : \|T\| \to P$ satisfying $f(\|t\|) \equiv g(t)$ for all $t : T$.\textsuperscript{47} A useful consequence of this recursion principle is that, for any proposition $P$, precomposition with $\|\|$ is an equivalence of type

$$\(|\|T\|| \to P\) \simeq (T \to P).$$

This is called the universal property of propositional truncation.

**Definition 2.16.2.** Let $T$ be a type. We call $T$ non-empty if we have an element of $\|T\|$.\textsuperscript{48}

When we view propositional truncation as an operation on types, the type of $\|\|$ is $\mathcal{U} \to \mathcal{U}$. However, that view does not take into account that $\|T\|$ is a proposition. It is more informative to pack this information into the codomain of the operation and let $\|\|$ have the type $\mathcal{U} \to \Sigma_{X : \mathcal{U}} \text{isProp}(X)$. The type $\Sigma_{X : \mathcal{U}} \text{isProp}(X)$ is also denoted as $\text{Prop}_{\mathcal{U}}$ and even as Prop. See Definition 2.20.10 for more information.

\textsuperscript{46}The name “truncation” is slightly misleading since it suggests leaving something out, whereas the correct intuition is one of adding identifications so everything becomes equal.

\textsuperscript{47}Given $t, t' : T$, we have an identification of type $\|t\| \simeq \|t'\|$. The existence of the function $g$ implies that we have an identification of type $g(\|t\|) \simeq g(\|t'\|)$, and hence an identification of type $f(\|t\|) \simeq f(\|t'\|)$. Thus a necessary condition for the existence of $g$ is the existence of identifications of type $f(\|t\|) \simeq f(\|t'\|)$. That justifies the hypothesis that $P$ is proposition.

\textsuperscript{48}We may alternatively say that $T$ is inhabited, in order to avoid confusion with the concept of $T$ not being empty, which would be represented by the proposition $\neg(T \simeq \emptyset)$, which is equivalent to $\neg\neg T$. 
Now that propositional truncation is available, we are ready to define logical disjunction and existence.

**Definition 2.16.3.** Given propositions $P$ and $Q$, define their disjunction by $(P \lor Q) \equiv \|P \lor Q\|$. It expresses the property that $P$ is true or $Q$ is true.

**Definition 2.16.4.** Given a type $X$ and a family $P(x)$ of propositions parametrized by a variable $x$ of type $X$, define a proposition that encodes the property that there exists a member of the family for which the property is true by $(\exists x : X P(x)) \equiv \|\sum x : X P(x)\|$. It expresses the property that there exists an element $x : X$ for which the property $P(x)$ is true; the element $x$ is not given explicitly.

The following logical quantifier could have been defined earlier, since it doesn’t use propositional truncation. We present it now, for completeness.

**Definition 2.16.5.** Given a type $X$ and a family $P(x)$ of propositions parametrized by a variable $x$ of type $X$, define a proposition that encodes the property that there exists a unique member of the family for which the property is true by the proposition $(\exists! x : X P(x)) \equiv \text{isContr}(\sum x : X P(x))$.

**Exercise 2.16.6.** Given $x : \|T\|$, prove that $\exists t : T (x = t)$.

**Exercise 2.16.7.** Suppose $P$ is a proposition. Produce an equivalence of type $P \Rightarrow \|P\|$.

The exercise above us to easily convert elements of type $\|P\|$ to elements of type $P$ when $P$ is a proposition.

**Definition 2.16.8.** Let $A$ be a type. For any element $a$ of $A$, the type $A(a) := \sum x : A \|a \rightarrow x\|$ is called the connected component of $a$ in $A$.\(^{49}\) We say that elements $x, y$ of $A$ are in the same component of $A$ if $\|x \rightarrow y\|$. The type $A$ is called connected\(^{50}\) if it is non-empty with all elements in the same component. Formally, this property is encoded by the following proposition.

$$\text{isConn}(A) := \|A\| \times \prod_{x, y : A} \|x \rightarrow y\|.$$ 

Note that the empty type $\emptyset$ is not connected.

One can view being connected as a weak form of being contractible – without direct access to a center and to identifications of elements.

**Exercise 2.16.9.** Show that the component of $a$ in $A$ is connected. Show that elements in the same component have the same propositional properties, that is, for any $P : A \rightarrow \text{Prop}$, $P(x) \rightarrow P(y)$ for any $x, y : A$ with $\|x = y\|$.

**Exercise 2.16.10.** Show that any connected set is contractible.

**Exercise 2.16.11.** Let $A$ be a connected type, and suppose that $a \rightarrow a$ is a proposition for every $a : A$. Show that $A$ is contractible.

**Exercise 2.16.12.** Show that $\sum x : A B(x)$ is connected when $A$ is connected and $B(x)$ is connected for any $x : A$.

In the following definition we introduce the adverb merely, which serves as a quicker way to say the propositional truncation of in English speech.
2.17 More on equivalences; surjections and injections

In this section we collect a number of useful results on equivalences.

Consider the function $f : 1 \to 2$ that is constant 0. The fibers of $f$ at 0 and 1 are $\sum_{x : 1} 0 \simeq 0$ and $\sum_{x : 1} 1 \simeq 0$, respectively. The latter fiber is not contractible: having an element of it would mean having an element of $1 \simeq 0$, which would in turn lead to an element in False (using a similar reasoning as in Section 2.12.1). Hence $f$ is not an equivalence. Observe that both fibers are propositions, that is, contain at most one element.

As a function between sets $f$ is an injection (one-to-one), but not a surjection. We need these important concepts for types in general. We define them as close as possible to their usual meaning in set theory: a function from $A$ to $B$ is surjective if the preimage of any $b : B$ is non-empty, and injective if such preimages contain at most one element. This motivates the following definitions.

**Definition 2.17.1.** A function $f : A \to B$ is a **surjection**, or is **surjective**, if for all $b : B$ there exists an $a : A$ such that $b \leadsto f(a)$, that is, $\exists_{a : A}(b \leadsto f(a))$.  

**Definition 2.17.2.** A function $f : A \to B$ is an **injection**, or is **injective**, if $f^{-1}(b)$ is a proposition for all $b : B$. The property of being an injection is encoded by the type isInj($f$) $\equiv \prod_{b : B} \text{isProp}(f^{-1}(b))$.

**Exercise 2.17.3.** Show that if $A, B$ are sets, then a function $f : A \to B$ is injective if and only if $f(a) \leadsto f(a')$ implies $a \leadsto a'$ for all $a, a'$.

**Lemma 2.17.4.** For all types $A, B$, a function $f : A \to B$ is an equivalence if and only if $f$ is an injection and a surjection.

**Proof.** If $f : A \to B$ is an equivalence, then all fibers are contractible, so $f$ is both an injection and a surjection. Conversely, if $f$ is both injective and surjective, we show that $f^{-1}(b)$ is contractible, for each $b : B$. Being contractible is a proposition, so by Definition 2.16.1 we can drop the truncation in $\|\sum_{x : A} b \leadsto f(a)\|$. Now apply injectivity.  

If the types $A$ and $B$ in the above lemma are **sets**, then we call equivalences between $A$ and $B$ also **bijections**.

**Corollary 2.17.5.** Let $A, B$ be types such that $A$ is non-empty and $B$ is connected. Then any injection $f : A \to B$ is an equivalence.

**Proof.** By Lemma 2.17.4 it suffices to show that $f$ is surjective. This is a proposition, so by Definition 2.16.1 and $\|A\|$ we may assume $a : A$, so $f(a) : B$. By $\prod_{x, y : B} \|x \leadsto y\|$ we now get that all preimages under $f$ are non-empty.

**Lemma 2.17.6.** Let $f : X \to Y$ be a surjective map from a connected type $X$. Then $Y$ is connected too.

---

51 A function $f : A \to B$ is a split surjection if for all $b : B$ we have an $a : A$ with $b \leadsto f(a)$, in other words, we have a function of type $\prod_{b : B} \sum_{a : A}(b \leadsto f(a))$. This is equivalent to saying we have a function $g : B \to A$ such that $f \circ g \simeq \text{id}_{B}$ (such a $g$ is called a section of $f$).

52 This argument applies generally: Any non-empty proposition is contractible.
Proof. For any map \( f : X \to Y \) between arbitrary types, if \( y, y' : Y \) and we are given \( x, x' : X \), \( p : y \rightsquigarrow f(x) \), \( p' : y' \rightsquigarrow f(x') \) and \( q : x \rightsquigarrow x' \), then we have a path between \( y \) and \( y' \) given by the composite

\[
y \xrightarrow{p} f(x) \xrightarrow{f(q)} f(x') \xrightarrow{p'} y'.
\]

Now the lemma follows by eliminating the propositional truncations in the assumptions, using that the conclusion is a proposition. \( \square \)

Construction 2.17.7. For every \( f : A \to B \), \( b : B \), and \( z, z' : f^{-1}(b) \), there is an equivalence

\[
(z \rightsquigarrow z') \rightsquigarrow \text{ap}_f^{-1}(\text{snd } z' \cdot \text{snd } z^{-1}).
\]

Implementation of Construction 2.17.7. We can construct this equivalence for \( z \equiv (a, p) \) and \( z' \equiv (a', p') \), where \( a, a' : A \), \( p : b \rightsquigarrow f(a) \) and \( p' : b \rightsquigarrow f(a') \), as the composition

\[
(z \rightsquigarrow z') \equiv ((a, p) \rightsquigarrow (a', p'))
\]

\[
\xrightarrow{\sum_{q : a \to a'} p \xrightarrow{q} p'}
\]

\[
\xrightarrow{\sum_{q : a \to a'} \text{ap}_f(q) \cdot p \rightsquigarrow p'}
\]

\[
\text{ap}_f^{-1}(p' \cdot p^{-1}).
\]

The second equivalence relies on Definition 2.7.3 and Construction 2.14.3.

Lemma 2.17.8. A function \( f : A \to B \) is an injection if and only if each induced function \( \text{ap}_f : (a \rightsquigarrow a') \to (f(a) \rightsquigarrow f(a')) \) is an equivalence, for all \( a, a' : A \).\(^5\)

Proof. It follows directly from (2.17.1) that if \( \text{ap}_f \) is an equivalence, then \( f^{-1}(b) \) is a proposition, as all its identity types are contractible.

On the other hand, if we fix \( a, a' : A \) and \( p : f(a) \rightsquigarrow f(a') \), then (2.17.1) applied to \( b \equiv f(a) \), \( z \equiv (a, \text{refl}_{f(a)}) \) and \( z' \equiv (a', p) \), gives \( \text{ap}_f^{-1}(p) \rightsquigarrow (z \rightsquigarrow z') \), which shows that if each \( f^{-1}(b) \) is a proposition, then \( \text{ap}_f \) is an equivalence. \( \square \)

Corollary 2.17.9. Let \( A \) and \( B \) be types and let \( f : A \to B \) be a function. Then we have:

1. All fibers of \( f \) are \( n+1 \)-types if and only if all fibers of each map induced by \( f \) on identity types are \( n \)-types;
2. If \( A \) and \( B \) are connected, then \( f \) is an equivalence if and only if each map induced by \( f \) on identity types is an equivalence;
3. If \( A \) and \( B \) are connected and \( a : A \), then \( f \) is an equivalence if and only if \( \text{ap}_f : (a \rightsquigarrow a) \to (f(a) \rightsquigarrow f(a)) \) is an equivalence.

Proof. (1) When \( n \) is \(-2\) this is Lemma 2.17.8 and the proof for \( n \geq -1 \) is similar. (2) By Lemma 2.17.8 and Corollary 2.17.5. (3) By (2) and Exercise 2.16.9. \( \square \)
Exercise 2.17.10. Let \( A, B : \mathcal{U}, F : A \to \mathcal{U} \) and \( G : B \to \mathcal{U} \), and \( f : A \xrightarrow{\sim} B \) and \( g : \prod_{a : A} F(a) \xrightarrow{\sim} G(f(a)) \). Give an equivalence from \( \sum_{a : A} F(a) \) to \( \sum_{b : B} G(b) \). (An important special case is \( F \equiv G \circ f \).) 

Another application of propositional truncation is the notion of image.

**Definition 2.17.11.** Let \( A, B \) be types and let \( f : A \to B \). We define the image of \( f \) as

\[
\text{im}(f) : \equiv \sum_{y : B} \exists x : A \,(y \to f(x)).
\]

Note that \( (\exists x : A \,(y \xrightarrow{\sim} f(x))) \equiv \|f^{-1}(y)\| \), the propositional truncation of the fiber. For this reason, \( \text{im}(f) \) is called the *propositional image*. Later we will meet other notions of image, based on other truncation operations.

Exercise 2.17.12. Show that the image of \( f : A \to B \) induces a factorization \( f \xrightarrow{\sim} \pi \circ p \), visualized by the following diagram:\footnote{This diagram actually commutes by definition.}

\[
\begin{array}{ccc}
A & \xrightarrow{f} & B \\
\downarrow{p} & & \downarrow{i} \\
\text{im}(f) & & \\
\end{array}
\]

where \( p \) is surjective and \( i \) is injective. Show that the following type of image factorizations of \( f : A \to B \) is contractible:

\[
\sum_{C : \mathcal{U}} \sum_{g : A \to C} \sum_{h : C \to B} \left( (f \xrightarrow{\sim} h \circ g) \times \text{isSurj}(g) \times \text{isInj}(h) \right).
\]

Exercise 2.17.13. Let \( A \) be a type and \( B \) as set and \( f : A \to B \). Show that \( \text{im}(f) \) is a set.

Exercise 2.17.14. Let \( f : A \to B \) for \( A \) and \( B \) types, and let \( P(b) \) be a proposition depending on \( b : B \). Show that \( \prod_{z : \text{im}(f)} P(f(z)) \) if and only if \( \prod_{a : A} P(f(a)) \).

2.18 Decidability, excluded middle and propositional reszing

Recall from Lemma 2.15.4(6) that \( P \equiv P \) is a proposition whenever \( P \) is a proposition.

**Definition 2.18.1.** A proposition \( P \) is called *decidable* if \( P \equiv \neg P \) holds.

In traditional mathematics, it is usually assumed that every proposition is decidable. This is expressed by the following principle, commonly abbreviated LEM.

**Principle 2.18.2 (Law of Excluded Middle).** For every proposition \( P \), the proposition \( P \equiv \neg P \) holds.

(The “middle” ground excluded by this principle is the possibility that there is a proposition that is neither true nor false.)

Type theory is born in a constructivist tradition which aims at developing as much mathematics as possible without assuming the Law of Excluded Middle.\footnote{Besides any philosophical reasons, there are several pragmatic reasons for developing constructive mathematics. One is that proofs in constructive mathematics can be executed as programs, and another is that the results also hold in non-standard models, for instance a model where every type has a topological structure, and all constructions are continuous. See also Footnote 14.} Following this idea, we will explicitly state whenever we are assuming the Law of Excluded Middle.

Exercise 2.18.3. Show that the Law of Excluded Middle is equivalent to asserting that the map \( \text{yes} = \_ : \text{Bool} \to \text{Prop} \) is an equivalence.
A useful consequence of the Law of Excluded Middle is the principle of "proof by contradiction": to prove a proposition $P$, assume its negation $\neg P$ and derive a contradiction. Without the Law of Excluded Middle, this proves only the double negation of $P$, that is $\neg\neg P$. However, with the Law of Excluded Middle, one can derive $P$ from the latter: indeed, according to the Law of Excluded Middle, either $P$ or $\neg P$ holds; but $\neg P$ leads to a contradiction by hypothesis, making $P$ hold necessarily.

Exercise 2.18.4. Show that, conversely, LEM follows from the principle of double-negation elimination: For every proposition $P$, if $\neg\neg P$, then $P$ holds.

Remark 2.18.5. We will later encounter a weaker version of the Law of Excluded Middle, called the Limited Principle of Omniscience (Principle 3.6.21), which is often enough.56

Sometimes we make use of the following, which is another consequence of the Law of Excluded Middle:

Principle 2.18.6 (Propositional Resizing). For any pair of nested universes $\mathcal{U} : \mathcal{U}'$, the map $(P \mapsto P) : \text{Prop}_\mathcal{U} \to \text{Prop}_{\mathcal{U}'}$ is an equivalence.58

Exercise 2.18.7. Show that if the Law of Excluded Middle holds, then Propositional Resizing holds.

2.19 The replacement principle

In this section we fix a universe $\mathcal{U}$. We think of types $A : \mathcal{U}$ as small compared to arbitrary types, which are then large in comparison.59 Often we run into types that are not in $\mathcal{U}$ (small) directly, but are nevertheless equivalent to types in $\mathcal{U}$.

Definition 2.19.1. We say that a type $A$ is essentially $\mathcal{U}$-small if we have a type $X : \mathcal{U}$ and an equivalence $A \cong X$. And $A$ is locally $\mathcal{U}$-small if all its identity types are essentially $\mathcal{U}$-small.

Note that $\sum X : \mathcal{U}(A \cong X)$, the type expressing that $A$ is essentially $\mathcal{U}$-small, is a proposition by the univalence axiom for $\mathcal{U}$. Of course, any $A : \mathcal{U}$ is essentially $\mathcal{U}$-small, and any essentially $\mathcal{U}$-small type is locally $\mathcal{U}$-small.

To show that a type is locally $\mathcal{U}$-small we have to give a reflexive relation $\text{Eq}_A : A \to A \to \mathcal{U}$ that induces, by path induction, a family of equivalences $(x \cong y) \cong \text{Eq}_A(x, y)$.

Exercise 2.19.2. Show that $\mathcal{U}$ is locally $\mathcal{U}$-small, and investigate the closure properties of essentially and locally $\mathcal{U}$-small types. (For instance, show that if $A : \mathcal{U}$ and $B(x)$ is a family of locally $\mathcal{U}$-small types parametrized by $x : A$, then $\prod_{x : A} B(x)$ is locally $\mathcal{U}$-small.)

Remark 2.19.3. Note that propositional resizing (Principle 2.18.6) equivalently says that any proposition is essentially $\mathcal{U}$-small, where we may take $\mathcal{U}$ to be the smallest universe $\mathcal{U}_0$. When we assume this, we get that any set is locally $\mathcal{U}_0$-small.

We will make use of the following principle (recall the definition of the image, Definition 2.17.11).
When no confusion can arise, we simply write $\times$.

This follows from our replacement principle, assuming propositional resizing, or the even stronger principle of the excluded middle.

The replacement principle can be proved using the join construction of the image, cf. Rijke\(^{61}\), which uses as an assumption that the universes are closed under pushouts.\(^61\)

**Exercise 2.19.5.** Show that the replacement principle implies that for any locally $\mathcal{U}$-small type $A$, and any element $a : A$, the connected component $A(a)$ is essentially $\mathcal{U}$-small.

Another consequence is that the type of finite sets, which we’ll define below in Definition 2.24.5, is essentially small.

### 2.20 Predicates and subtypes

In this section, we consider the relationship between predicates on a type $T$ and subtypes of $T$. The basic idea is that the predicate tells whether an element of $T$ belongs to the subtype. Conversely, the predicate can be recovered from the subtype by asking whether an element of $T$ is in it.

**Definition 2.20.1.** Let $T$ be a type and let $P(t)$ be a family of propositions parametrized by an variable $t : T$. Then we call $P$ a predicate on $T$.\(^{62}\) If $P(t)$ is a decidable proposition, then we say that $P$ is a decidable predicate on $T$.

By Exercise 2.18.3, the decidable predicates $P$ on $T$ correspond uniquely to the characteristic functions $\chi_P : T \to \text{Bool}$.

We recall from Definition 2.17.2 the notion of injection, which will be key to saying what a subtype is.

**Definition 2.20.2.** A subtype of a type $T$ is a type $S$ together with an injection $f : S \to T$. Selecting a universe $\mathcal{U}$ as a repository for such types $S$ allows us to introduce the type of subtypes of $T$ in $\mathcal{U}$ as follows.

$$\text{Sub}_T^{\mathcal{U}} \equiv \sum_{S : \mathcal{U}} \sum_{f : S \to T} \text{isInj}(f).$$

When no confusion can arise, we simply write $\text{Sub}_T$ for $\text{Sub}_T^{\mathcal{U}}$.

**Exercise 2.20.3.** Show that $\text{Sub}_T$ is a set, for any type $T$. Hint: given subtypes $T_f \equiv (S, f, p)$ and $T_{f'} \equiv (S', f', p')$ of $T$, show that $T_f = T_{f'}$ amounts to finding a (unique) equivalence $e : S \simeq S'$ such that $f = f' \circ e$.

See the diagram in the margin.

**Lemma 2.20.4.** Let $T$ be a type and $P$ a predicate on $T$. Consider $\sum_{t : T} P(t)$ and the corresponding projection map $\text{fst} : T_P \equiv \left( \sum_{t : T} P(t) \right) \to T$. Then $\text{ap}_{\text{fst}} : (x, p_1) \mapsto (x, p_2)) \to (x_1 \mapsto x_2)$ is an equivalence, for any elements $(x_1, p_1)$ and $(x_2, p_2)$ of $T_P$.

**Proof.** We apply Construction 2.9.9. Consider $q : x_1 \mapsto x_2$. By induction on $q$, using Exercise 2.15.9, we get that each $p_1 \mapsto q$ is contractible, say

---

\(^{61}\)Pushouts are certain higher inductive types that suffice to construct all the higher inductive types that we need, but we don’t actually need them in this book.

\(^{62}\)Note that giving a predicate on $T$ is equivalent to giving a map $Q : T \to \text{Prop}_{\mathcal{U}}$ for a suitable universe $\mathcal{U}$, and we sometimes say that $Q$ itself is the predicate.

---
with center \(c_q\). We show that mapping \(q\) to \((q, c_q)\) defines an inverse of \(ap_{\text{fst}}\), applying Lemma 2.10.3 and the remarks after its proof. These give identifications in \(ap_{\text{fst}} (q, c_q) \simeq q\) for all \(q : x_1 \to x_2\). Also, for any \(r : (x_1, p_1) \to (x_2, p_2)\) we have an identification in \(r \simeq (\text{fst}(r), \text{snd}(r))\). The latter pair can be identified with \((ap_{\text{fst}(r)} c)\) for any \(c\) in the contractible type \(p_1 \equiv_{\text{fst}(r)} p_2\).

Combined with Lemma 2.17.8, this gives that \(\text{fst}\) is an injection. Hence, given a predicate \(P\) on \(T\), the subtype of \(T\) characterized by \(P\) is defined as \(T_P \equiv \sum_t P(t)\), together with the injection \(\text{fst} : T_P \to T\).

The lemma above has other important consequences.

**Corollary 2.20.5.** For each natural number \(n\), if \(T\) is a \(n\)-type, then \(T_P\) is also a \(n\)-type.

In particular, if \(T\) is a set, then \(T_P\) is again a set; we then call \(T_P\) a subset of \(T\) and we may denote it by \(\{ t : T \mid P(t) \}\).

It is important to distinguish between \(T_P\) as a sum type and as the triple \((T_P, \text{fst}, p)\), with \(p\) witnessing that \(\text{fst}\) is an injection. The latter triple is of type \(\text{Sub} T\), whereas \(T_P\) as a sum type is an element of some universe. It will always be clear from the context which one we mean when we use the notation \(T_P\).

**Exercise 2.20.6.** Let \(T\) be a set, and \(S_0\) and \(S_1\) be subsets of \(T\) with respective inclusions \(\text{fst}_0 : S_0 \to T\) and \(\text{fst}_1 : S_1 \to T\). Prove that the type

\[
\sum_f f : S_0 \to S_1 \quad \text{is a proposition. This proposition is denoted } S_0 \subseteq S_1.
\]

Thus the type of \(\subseteq\) is \(\text{Sub} T \to \text{Sub} T \to \text{Prop}\), and \(\text{Sub} T\) is a set by Exercise 2.20.3. Prove that the relation \(\subseteq\) is a partial order\(^\text{63}\) with a least and a greatest element (even if \(T\) is the empty type).

**Exercise 2.20.7.** Let \(T\) and \(X\) be types, \(f : X \to T\) a function, and \(P : T \to \text{Prop}\) a predicate. Construct an equivalence from the proposition \(\prod_x X \overset{P(f(x))}{\to} \text{type}\) to the type

\[
\sum_{g : X \to \sum_x P(t)} f \simeq \text{fst} \circ g.
\]

We may call this result the *universal property of subtypes.*

**Remark 2.20.8.** Another important consequence of Lemma 2.20.4 is that we can afford not to distinguish carefully between elements \((t, p)\) of the subtype \(T_P\) and elements \(t\) of type \(T\) for which the proposition \(P(t)\) holds. We will hence often silently coerce from \(T_P\) to \(T\) via the first projection, and if \(t : T\) is such that \(P(t)\) holds, we’ll write \(t : T_P\) to mean any pair \((t, p)\) where \(p : P(t)\), since when \(P(t)\) holds, the type \(P(t)\) is contractible.

Given a set \(A\) and a function \(\chi_B : A \to \text{Bool}\), Lemma 2.15.3 yields that \(\chi_B(a) = \text{yes}\) is a proposition, and we can form the subset \(\{ a : A \mid \chi_B(a) = \text{yes} \}\). However, not every subset as in Definition 2.20.2 can be given through a \(\chi_B : A \to \text{Bool}\). As proved in Section 2.12.1, any element of \(\text{Bool}\) is equal to \(\text{yes}\) or \(\text{no}\).

If \(P : A \to \mathcal{U}\) is a decidable predicate, then we can define \(\chi_P : A \to \text{Bool}\) by induction (actually, only case distinction) on \(p : P(a)\), setting \(\chi_P(a) = \text{yes}\) if \(p \equiv \text{inl}_-\) and \(\chi_P(a) = \text{no}\) if \(p \equiv \text{inr}_-\). We will often use a

\[\frac{}{T : \text{Prop} \vdash \text{fst} : T \to \text{Prop}}\]

Alternatively, one uses that \(\text{fst}^{-1}(t) = P(t)\) for all \(t : T\).
characteristic function \( T \rightarrow \text{Bool} \) to specify a decidable predicate on a type \( T \).

**Exercise 2.20.9.** Show that \( f(t) = \text{yes} \) is a decidable predicate on \( T \), for any type \( T \) and function \( f : T \rightarrow \text{Bool} \). Show \( (P \rightarrow \text{True}) \cup (P \rightarrow \text{False}) \) is a true proposition for every decidable proposition \( P \).

We’ve seen how to make a subtype from a predicate. Conversely, from a subtype of \( T \) given by the injection \( f : S \rightarrow T \), we can form a predicate \( P_f : T \rightarrow \text{Prop} \) defined by \( P_f(x) \equiv f^{-1}(x) \). We shall see in Construction 2.25.6 ((2)) that these operations form an equivalence between predicates on \( T \) and subtypes of \( T \).

**Definition 2.20.10.** The type of types that are propositions and the type of types that are sets are defined as:

\[
\text{Prop}_U \equiv \sum_{X : U} \text{isProp}(X) \quad \text{and} \quad \text{Set}_U \equiv \sum_{X : U} \text{isSet}(X).
\]

Both \( \text{Prop}_U \) and \( \text{Set}_U \) are subtypes of \( U \), and both are types in a universe one higher than \( U \).

When we don’t care about the precise universe \( U \), we’ll leave it out from the notation, and just write Prop and Set.

Following Remark 2.20.8, if we have a type \( A \) for which we know that it is a proposition or a set, we write also \( A : \text{Prop} \) or \( A : \text{Set} \), respectively.

**Definition 2.20.11.** A type \( A \) is called a **decidable set** if the identity type \( x \rightarrow y \) is a decidable proposition for all \( x, y : A \).

Note the slight subtlety of this definition together with Definition 2.18.1: Any proposition has decidable identity types (since each instance is contractible) and is thus a decidable set, even though it may not be a decidable as a proposition.

The way we phrased this definition implies that \( A \) is a set. The following celebrated and useful theorem states that this is unnecessary.

**Theorem 2.20.12** (Hedberg). Any type \( A \) for which we have a function of type \( \prod_{x,y:A} ((x \rightarrow y) \cup (x \rightarrow \neg y)) \) is a decidable set.

For a proof see Theorem 7.2.5 of the HoTT Book.

### 2.21 Pointed types

Sometimes we need to equip types with additional structure that cannot be expressed by a proposition such as \( \text{isProp}(X) \) and \( \text{isSet}(X) \) above. Therefore the following is not a subtype of \( U \).

**Definition 2.21.1.** A **pointed type** is a pair \((A,a)\) where \( A \) is a type and \( a \) is an element of \( A \). The **type of pointed types** is

\[
\mathcal{U}, \equiv \sum_{A : U} A.
\]

Given a type \( A \) we let \( A_+ \) be the pointed type you get by adding a default element: \( A_+ \equiv (A \cup \text{True}, \text{inr}_\text{inv}) \). Given a pointed type \( X \equiv (A,a) \), the **underlying type** is \( X_- \equiv A \), and the **base point** is \( \text{pt}_X \equiv a \), so that \( X \equiv (X_-, \text{pt}_X) \).

Let \( X \equiv (A,a) \) and \( Y \equiv (B,b) \) be pointed types. Define the map \( \text{ev}_a : (A \rightarrow B) \rightarrow B \) by \( \text{ev}_a(f) \equiv f(a) \). Then the fiber of \( \text{ev}_a \) at \( b \) is the

---

65The obelus \( \div \) is sometimes used to denote division, but is also used to for subtraction, especially in Northern Europe. This inspired our use, considering its “adjoint” relationship to \( + \) detailed in Exercise 2.21.4.
type $\text{ev}_a^{-1} \equiv \sum_f : A \to B (b \xrightarrow{=} f(a))$. The latter type is also called the type of pointed functions from $X$ to $Y$ and denoted by $X \to pt_Y$. In the notation above,

$$ (X \to pt_Y) \equiv \sum_{f : X \to pt_Y} (pt_{pt_Y} \xrightarrow{} f(pt_X)). $$

Given a pointed function $g \equiv (f, p)$, the underlying function is $g_* \equiv f$, and the pointing path is $g_{pt} \equiv p$, so that $g \equiv (g_*, g_{pt})$.

If $Z$ is also a pointed type, and we have pointed functions $f : X \to pt_Y$ and $g : Y \to pt_Z$, then their composition $gf : X \to pt_Z$ is defined as the pair $(g \cdot f_*, g \cdot (f_{pt} g_{pt}))$, as illustrated below:\textsuperscript{66}

$$
\begin{array}{ccc}
pt_Y & \xrightarrow{f_{pt}} & f_*(pt_X) \\
\downarrow{\scriptstyle g_\ast} & & \downarrow{\scriptstyle g} \\
pt_Z & \xrightarrow{g \cdot (f_{pt} g_{pt})} & g_*(f_{pt} g_{pt})
\end{array}
$$

We may also use the notation $g \circ f$ for the composition.

**Definition 2.21.2.** If $X \equiv (A, a)$ is a pointed type, then we define the pointed identity map $\text{id}_X : X \to X$ by setting $\text{id}_X : (\text{id}_A, \text{refl}_a)$.

**Remark 2.21.3.** If $X$ is a pointed type, then $X_*$ is a type, but $X$ itself is not a type. It is therefore unambiguous, and quite convenient, to write $x : X$ for $x : X_*$, and $X \to \U$ for $X_\to \U$. Likewise, we can write $f : X \to Y$ for $f_* : X_* \to Y_*$. In that case we still write $f_{pt} : pt_X \xrightarrow{=} f(pt_X)$ for the witness of pointedness.

**Exercise 2.21.4.** If $A$ is a type and $B$ is a pointed type, give an equivalence from $A \to B_*$ to $A_+ \to B$.

**Exercise 2.21.5.** Let $A$ be a pointed type and $B$ a type. Give an equivalence from $\sum_{b : B} (A \to (B, b))$ to $(A \to B)$.

Since $\U$ and $X \to Y$ are sum types, the results on identifying pairs in Section 2.10 apply to pointed types and pointed maps as well.

**Definition 2.21.6.** If $X$ and $Y$ are pointed types, we define the type of pointed equivalences from $X$ to $Y$ as:

$$ X \xrightarrow{\sim} Y \equiv \sum_{f : X \to Y} \text{isEquiv}(f_\ast) $$

**Exercise 2.21.7.** From an identification of pointed types $p : X \xrightarrow{\sim} Y$, construct an identification of the underlying types, $p_* : X_* \xrightarrow{\sim} Y_*$, as well as an identification $q : pt_Y \xrightarrow{\sim} p_*(pt_X)$. Together, this gives a map of type

$$(X \xrightarrow{\sim} Y) \to (X_* \xrightarrow{\sim} Y_*).$$

Show that this is an equivalence.

### 2.22 Operations that produce sets

The following lemma holds for $n$-types in general, but we only need it for propositions and sets.

**Lemma 2.22.1.** Let $X$ and $Y$ be types.

1. If $X$ and $Y$ are propositions, then so are $X \to Y$ and $X \xrightarrow{\sim} Y$. In other words, Prop is a set.
(2) If $X$ and $Y$ are sets, then so are $X \xrightarrow{\approx} Y$ and $X \xrightarrow{\approx} Y$. In other words, Set is a groupoid.

Proof. By univalence, $X \xrightarrow{\approx} Y$ and $X \xrightarrow{\approx} Y$ are equivalent, whereas the latter is equal by definition to $\sum_{f:X \to Y} \text{isEquiv}(f)$. If $X$ and $Y$ are propositions (sets), then by Lemma 2.15.5 also $X \to Y$ is a proposition (set). Moreover, $\text{isEquiv}(f)$ is a proposition by Lemma 2.15.7. Now the lemma follows by Corollary 2.20.5. \qed

One may wonder whether $\mathbb{N}$ as defined in Section 2.12 is a set. The answer is yes, but it is harder to prove than one would think. In fact we have the following theorem.

**Theorem 2.22.2.** All inductive types in Section 2.12 are sets if all constituent types are sets.

Proof. We only do the case of $\mathbb{N}$ and leave the other cases to the reader (cf. Exercise 2.22.3). The following proof is due to Simon Huber. We have to give identifications of type $p \xrightarrow{\approx} q$ for all $n, m : \mathbb{N}$ and $p, q : n = m$. By induction on $q$ it suffices to give identifications of type $p \xrightarrow{\approx} \text{refl}_n$ for all $p : n \xrightarrow{\approx} n$. Note that this cannot simply be done by induction on $p$. Instead we first give an inversion principle for identifications in $\mathbb{N}$ as follows. Define a type $T(n, m, p)$ for $n, m : \mathbb{N}$ and $p : n = m$ by induction on $n$ and $m:

$$T(0, 0, p) \equiv (p \xrightarrow{\approx} \text{refl}_0) \text{ and } T(\text{succ}(n), \text{succ}(m), p) \equiv \text{ap}^{-1}_{\text{succ}}(p),$$

and for the other cases the choice does not matter, say $T(0, \text{succ}(m), p) \equiv T(\text{succ}(n), 0, p) \equiv 0$. Next we give elements of type $T(n, m, p)$ for all $n, m$, and $p$ by induction on $p$, reducing to $T(n, n, \text{refl}_n)$ for all $n : \mathbb{N}$, which we deal with by distinguishing cases on $n$. For $n \equiv 0$ we use $\text{refl}_0$ and for the case $\text{succ}(n)$ we use the pair $(\text{refl}_n, \text{refl}_{\text{succ}(n)})$, noting that $\text{ap}^{-1}_{\text{succ}}(\text{refl}_n) \equiv \text{refl}_{\text{succ}(n)}$.

We can now give identifications of type $p \xrightarrow{\approx} \text{refl}_n$ for all $p : n \xrightarrow{\approx} n$ by induction on $n$. For $n \equiv 0$ we use the element of $T(0, 0, p)$ constructed above. For the case $\text{succ}(n)$, the element of $T(\text{succ}(n), \text{succ}(n), p)$ constructed above yields a pair $(q, r)$ with $q : n \xrightarrow{\approx} n$ and $r : p \xrightarrow{\approx} \text{ap}_{\text{succ}}(q)$. By induction hypothesis we have and identification $e : q \xrightarrow{\approx} \text{refl}_n$. We get the desired identification by concatenating $r$ and $\text{ap}_{\text{succ}}(e)$:

$$p \xrightarrow{\approx} \text{ap}_{\text{succ}}(q) \xrightarrow{\approx} \text{ap}_{\text{succ}}(\text{refl}_n) \equiv \text{refl}_{\text{succ}(n)}.$$

\qed

**Exercise 2.22.3.** Show that $X \amalg Y$ is a set if $X$ and $Y$ are sets.

Recall that propositional truncation is turning any type into a proposition by adding identifications of any two elements. Likewise, there is an operation turning any type into a set by adding (higher) identifications of any two identifications of any two elements. The latter operation is called set truncation. It is yet another example of a higher-inductive type.

**Definition 2.22.4.** Let $T$ be a type. The **set truncation** of $T$ is a type $\|T\|_0$ defined by the following constructors:

1. an element $|t|_0 : \|T\|_0$ for all $t : T$;
2. a identification $p \xrightarrow{\approx} q$ for all $x, y : \|T\|_0$ and $p, q : x \xrightarrow{\approx} y$. 

The (unnamed) second constructor ensures that \( \|T\|_0 \) is a set. The induction principle states that, for any family of sets \( S(x) \) defined for each \( x : \|T\|_0 \), in order to define a function \( f : \prod_{x : \|T\|_0} S(x) \), it suffices to give a function \( g : \prod_{t : T} S(\|t\|_0) \). Computationally, we get \( f(\|t\|_0) \equiv g(t) \) for all \( t : T \).

In the non-dependent case we get that for any set \( S \) and any function \( g : T \to S \) there is a unique function \( f : \|T\|_0 \to S \) satisfying \( f(\|t\|_0) \equiv g(t) \) for all \( t : T \). A consequence of this recursion principle is that, for any set \( S \), precomposition with \( \|\_\|_0 \) is an equivalence
\[
(\|T\|_0 \to S) \leftrightarrow (T \to S).
\]
This is called the universal property of set truncation.\(^{69}\)

**Exercise 2.22.5.** Let \( A \) be a type. Define for every element \( z : \|A\|_0 \) the connected component corresponding to \( z, A(z) \), a subtype of \( A \), such that for \( a : A \), you recover the notion from Definition 2.16.8: \( A(\|a\|_0) \equiv A(a) \).\(^{70}\)

Prove that the set truncation map \( \|\_\|_0 : A \to \|A\|_0 \) in this way exhibits \( A \) as the sum of its connected components, parametrized by \( \|A\|_0 \):

\[
A \sim \sum_{z : \|A\|_0} A(z).
\]

Prove that \( A \) is connected iff \( \|A\|_0 \) is contractible. \( \square \)

### 2.22.6 Weakly constant maps

The universal property of the propositional truncation, Definition 2.16.1, only applies directly to construct elements of propositions (that is, to prove them). Here we discuss how we can construct elements of sets.

**Definition 2.22.7.** A map \( f : A \to B \) is weakly constant if \( f(x) \sim f(x') \) for all \( x, x' : A \).

This is in contrast to a constant map, which can be identified with one of the form \( x \mapsto b \) for some \( b : B \). Any constant map is indeed weakly constant. Note also that when \( B \) is a set, weak constancy of \( f : A \to B \) is a proposition.

**Theorem 2.22.8.** If \( f : A \to B \) is a weakly constant map, and \( B \) is a set, then there is an induced map \( g : \|A\| \to B \) such that \( g(\|x\|) \equiv f(x) \) for all \( x : A \).

**Proof.** Consider the image factorization (Exercise 2.17.12) \( A \xrightarrow{p} \text{im}(f) \twoheadrightarrow B \) of \( f \), where \( p(x) \equiv (f(x), ((x, \text{refl}_{f(x)}))) \) and \( i(y, _) \equiv y \).

The key point is that \( \text{im}(f) \) is a proposition because \( f \) is weakly constant. First note that \( \text{im}(f) \) is a set by Exercise 2.17.13. Let \((y_1, z_1), (y_2, z_2) : \text{im}(f)\).

We have to prove \((y_1, z_1) = (y_2, z_2)\), which is a proposition. Hence we may hypothesize (by truncation induction on \( z \)) that we have \( x_1, x_2 : A \) with \( y_i = f(x_i) \) for \( i = 1, 2 \). Hence we get \( y_1 = f(x_1) = f(x_2) = y_2 \) and therefore \((y_1, z_1) = (y_2, z_2)\).

Thus, by the universal property of the truncation, we get \( g' : \|A\| \to \text{im}(f) \) such that \( g'(\|x\|) \equiv p(x) \equiv (f(x), ((x, \text{refl}_{f(x)}))) \). Composing with \( i \) we get \( g : \equiv i \circ g' : \|A\| \to B \) with \( g(\|x\|) \equiv f(x) \), as desired. \( \square \)
2.22.9 Set quotients

As an example, we first present an abstraction of the possible economical situations of a person as a quotient. Net worth can be defined as wealth minus debt. Let’s assume wealth \( w \) and debt \( d \) are natural numbers. The debt can be greater than the wealth, yielding a negative net worth, but at this point in our book we do not have negative numbers at our disposal. However, we do have the binary product, and the pair \((w, d) : (\mathbb{N} \times \mathbb{N})\) also completely determines the net worth. However, \((w, d)\) contains more information than necessary for the net worth: \((\text{succ}(w), \text{succ}(d))\), for example, determines the same net worth as \((w, d)\), and \((\text{succ}(w), \text{succ}(d)) \neq (w, d)\). But differently, the type \( \mathbb{N} \times \mathbb{N} \) does not capture the notion of net worth, since its identity types don’t capture equality of net worth.

Clearly, we need a different type to capture the notion of net worth. Of course, we want a type construction that works not only for the special case of net worth, but also in similar situations. Common to such situations is that we have a type \( A \) and an equivalence relation \( R : A \to A \to \text{Prop} \). In the example of net worth, we have \( A \equiv (\mathbb{N} \times \mathbb{N}) \), and the equivalence relation is \( R((w_1, d_1), (w_2, d_2)) \equiv (w_1 + d_2 = w_2 + d_1) \), precisely capturing equality of net worth, \( w_1 - d_1 = w_2 - d_2 \), without actually using subtraction and negative numbers.

What we need is a new type, which is like \( A \), but with \( R \) as equality. Note that the latter requires that the new type is a set. The quotient set \( A/R \) that we will define and study in this section fulfills these requirements. In the special case of \( A \equiv (\mathbb{N} \times \mathbb{N}) \), and \( R((w_1, d_1), (w_2, d_2)) \equiv (w_1 + d_2 = w_2 + d_1) \), the type \( A/R \) could in fact be used as a type of integers, cf. Section 3.2 and see Exercise 2.22.14.

**Definition 2.22.10.** Given a type \( A \) and an equivalence relation \( R : A \to A \to \text{Prop} \), we define the quotient set \( A/R \) as the image of the map \( R : A \to (A \to \text{Prop}) \). Indeed, \( A/R \) is a set, since \( \text{Prop} \) is a set, and so are \( A \to \text{Prop} \) and the image \( \sum_{\rho : A \to \text{Prop}} \exists x : A (\rho(x) = \text{refl}_A(x)) \) of \( R \). For \( a : A \) we define \([a] \equiv (\rho(a), (a, \text{refl}_A(a))) \) in \( A/R \); \([a] \) is called the equivalence predicate of \( a \).

Any element of the image of \( R \) is merely an equivalence predicate: a predicate \( P \) on \( A \) for which there exists \( a : A \) such that \( P(a) \) holds if and only if \( R(a, x) \) holds.

In the following proofs we frequently use Exercise 2.17.14.

**Lemma 2.22.11.** For any equivalence predicate \( P : A/R \) and \( a : A \), \( P \) and \([a] \) are equal if and only if \( P(a) \) holds.

**Proof.** Assume \( P \) and \([a] \) are equal. Then \( P(x) \) iff \( R(a, x) \) for all \( x : A \). Now take \( x \equiv a \) and use reflexivity \( R(a, a) \) to conclude \( P(a) \).

Conversely, assume \( P(a) \), and let \( x : A \) be given. To prove the proposition \( P(x) = R(a, x) \) we may assume that \( P \equiv [b] \) for some \( b : A \). Then \( P(x) \equiv R(b, x) \), and we need to show \( R(b, x) = R(a, x) \). This follows from \( P(a) \equiv R(b, a) \) using symmetry and transitivity.

The following theorem gives two important properties of the set quotient, the second is commonly called the universal property.
THEOREM 2.22.12. We have ([x] = [x']) if R(x, x') for all x, x' : A. Also, let B be a set and f : A → B a function such that f(x) = f(x') for all x, x' : A with R(x, x'). Then the type \( \Sigma_{x : A} / R \rightarrow 0 (\bar{f} = g \circ [\cdot]) \) is contractible. The diagram in the margin visualizes the situation. We will construct the center of contraction \( \tilde{f} : A / R \rightarrow B \) such that \( \tilde{f}(x) \equiv f(x) \) for all \( x : A \).

Proof. For the first part we use Lemma 2.22.11 applied to \( P \equiv [x] \) and \( x' \).

Now let B be a set and let \( f : A \rightarrow B \) a function satisfying \( f(x) = f(x') \) for all \( x, x' : A \) with \( R(x, x') \). We first define the center of contraction \( \bar{f} : A / R \rightarrow B \). To define \( \bar{f}(z) \) in B, we note that \( f \circ \text{fst} \) is weakly constant map of type \( \Sigma_{x : A} (P = [x]) \rightarrow B \). By Theorem 2.22.8 we get a map \( g : \exists y : A (P = [x]) \rightarrow B \) and we put \( \bar{f}(z) \equiv g(p) \).

We check the equality by definition: As an element of \( A / R \), equivalence predicate \([x] \) is accompanied by the witness \( p \equiv [(x, \text{refl}[x])] : \exists y : A ([x] = [y]) \). By Theorem 2.22.8, this is mapped by \( g \), by definition, to \( (f \circ \text{fst})(x, \text{refl}[x]) \equiv f(x) \), as desired.

Now, if \( g, h \) satisfy \( g \circ [\cdot] = f = h \circ [\cdot] \), then for any \( z : A / R \), the type \( g(z) = h(z) \) is a proposition since \( B \) is a set, so we may assume \( z \equiv [x] \) for some \( x : A \). Then \( g([x]) = f(x) = h([x]) \), as desired. \( \square \)

EXERCISE 2.22.13. Give an equivalence \( A / R \rightarrow ||A|| \) when \( R(x, y) \equiv \text{True} \) for all \( x, y : A \).\(^{74}\)

EXERCISE 2.22.14. Let \( A \equiv (N \times N) \) and \( R : A \rightarrow A \rightarrow \text{Prop} \) defined by \( R((w_1, d_1), (w_2, d_2)) \equiv (w_1 + d_2 = w_2 + d_1) \). Let \( Z \equiv \{(w, d) \mid (d = 0) \lor (w = 0) \lor (d = 0)\} \). Construct an equivalence \( f : A / R \rightarrow Z \) such that for all \( (w, d, p) : Z \) we have \( f([[w, d]]) = (w, d) \).\(^{75}\)

It is also possible to postulate\(^{76}\) the quotient set as a higher inductive type.

DEFINITION 2.22.15. Let \( A \) be a type and \( R : A \rightarrow A \rightarrow \text{Prop} \) an equivalence relation. Define the quotient \( A / R \) to be type with the following constructors:

1. a constructor \( s \) of type isSet(A / R) ensuring that \( A / R \) is a set;
2. an element constructor \([x] : A / R \) for all \( x : A \);
3. a constructor providing a proof \( r(x, y, p) \) of \([x] = [y] \) for all \( x, y : A \) and \( p : R(x, y) \).

Let \( B(z) \) be a set for every element \( z : A / R \). The induction principle for \( A / R \) states that, in order to define an element of \( B(z) \) for every \( z : A / R \), it suffices to give elements \( b_x : B([x]) \) for every \( x : A \). Together with a proof of the proposition \( b_x \xrightarrow{r(x, y, p)} b_y \) for all \( x, y : A \) and \( p : R(x, y) \). The function \( f \) thus defined satisfies \( f([x]) \equiv b_x \) for all \( x : A \).\(^{77}\)

EXERCISE 2.22.16. Give an equivalence between \( A / R \) as defined in Definition 2.22.10 and \( A / R \) as defined in Definition 2.22.15.\(^{78}\)

REMARK 2.22.17. We can use set quotients to give an alternative definition of the set truncation \( ||A||_0 \) of a type \( A \). Consider the relation \( R : A \rightarrow A \rightarrow \text{Prop} \) given by \( R(x, y) \equiv ||x \rightarrow y|| \). This is easily seen to be an equivalence relation, using refl, symm and trans from Section 2.5. Hence we get a quotient set \( A / R \) that satisfies \( ||x||_0 = ||y||_0 \Rightarrow ||x \rightarrow y|| \), for all
elements \(x\) and \(y\) of \(A\), where we write \([\_]_0\) for the equivalence predicates. Furthermore, Theorem 2.22.12 implies that \(A/R\) satisfies the recursion principle of Definition 2.22.4: If \(S\) is a set, and \(g : A \to S\) is any function, then \(g(x) = g(y)\) holds whenever \(\|x \sim y\|\) by the elimination principle of the propositional truncation, and hence we get a function \(f : A/R \to S\) satisfying \(f([x]_0) = g(x)\) for all \(x : A\), as desired.\(^{77}\)

2.23 More on natural numbers

A useful function \(\mathbb{N} \to \mathbb{N}\) is the predecessor \(\text{pred}\) defined by \(\text{pred}(0) \equiv 0\) and \(\text{pred}(\text{succ}(n)) \equiv n\). Elementary properties of addition, multiplication and predecessor can be proved in type theory in the usual way. We freely use them, sometimes even in definitions, leaving most of the proofs/constructions to the reader.

**Definition 2.23.1.** Let \(n, m : \mathbb{N}\). We say that \(m\) is less than or equal to \(n\), and write \(m \leq n\), if there is a \(k : \mathbb{N}\) such that \(k + m = n\). Such a \(k\) is unique, and if it is not 0, we say that \(m\) is less than \(n\), denoted by \(m < n\). Both \(m \leq n\) and \(m < n\) are propositions for all \(n, m : \mathbb{N}\).

**Exercise 2.23.2.** Try your luck in type theory proving any of the following. The successor function satisfies \((\text{succ}(n) = \text{succ}(m)) \simeq (n = m)\). The functions + and \(\cdot\) are commutative and associative, \(\cdot\) distributes over +. The relations \(\leq\) and \(<\) are transitive and preserved under +; \(\leq\) also under \(-\). We have \((m \leq n) \simeq ((m < n) \sqcup (m = n))\) (so \(\leq\) is reflexive). Furthermore, \(((m \leq n) \times (n \leq m)) \simeq (m = n)\), and \(\neg((m < n) \times (n < m))\) (so \(<\) is irreflexive).

We can prove the following lemma by double induction.

**Lemma 2.23.3.** The relations \(=\), \(\leq\) and \(<\) on \(\mathbb{N}\) are decidable.

By Hedberg’s Theorem 2.20.12, we get an alternate proof that \(\mathbb{N}\) is a set.

We will now prove an important property of \(\mathbb{N}\), called the **least number principle for decidable, non-empty subsets of \(\mathbb{N}\)**. We give some more details of the proof, since they illustrate an aspect of type theory that has not been very prominent up to now, namely the close connection between proving and computing.

**Construction 2.23.4.** Let \(P(n)\) be a proposition for all natural numbers \(n\). Define the type \(P_{\min}(n)\) expressing that \(n\) is the smallest natural number such that \(P(n)\):

\[
P_{\min}(n) \equiv P(n) \times \prod_{m : \mathbb{N}} (P(m) \to n \leq m)
\]

Then we seek a function

\[
(2.23.1) \quad \min(P) : \prod_{n : \mathbb{N}} (P(n) \sqcup \neg P(n)) \to \bigvee_{n : \mathbb{N}} P(n) \to \sum_{n : \mathbb{N}} P_{\min}(n),
\]

computing a minimal witness for \(P\) from evidence that \(P\) is decidable and that a witness exists.

**Implementation of Construction 2.23.4.** First note that \(P_{\min}(n)\) is a proposition, and that all \(n\) such that \(P_{\min}(n)\) are equal. Therefore the type \(\sum_{n : \mathbb{N}} P_{\min}(n)\) is also a proposition.

Given a function \(d(n) : P(n) \sqcup \neg P(n)\) deciding \(P(n)\) for each \(n : \mathbb{N}\), we define a function \(\mu_P : \mathbb{N} \to \mathbb{N}\) which, given input \(n\), searches for a \(k < n\)
such that $P(k)$. If such a $k$ exists, $\mu_P$ returns the least such $k$, otherwise $\mu_P(n) = n$. This is a standard procedure that we will call bounded search. The function $\mu_P$ is defined by induction, setting $\mu_P(0) \equiv 0$ and $\mu_P(\text{succ}(n)) \equiv \mu_P(n)$ if $\mu_P(n) < n$. Otherwise, we set $\mu_P(\text{succ}(n)) \equiv n$ if $P(n)$, and $\mu_P(\text{succ}(n)) \equiv \text{succ}(n)$ otherwise, using $d(n)$ to decide, that is, by induction on $d(n) : P(n) \text{I} \neg P(n)$. By design, $\mu_P$ 'remembers' where it has found the least $k$ (if so). We are now done with the computational part and the rest is a correctness proof.

By induction on $n : \mathbb{N}$ and $d(n) : P(n) \text{I} \neg P(n)$ we show

$$\mu_P(n) \leq n \quad \text{and} \quad \mu_P(n) < n \rightarrow P(\mu_P(n)).$$

The base case where $n \equiv 0$ is easy. For the induction step, review the computation of $\mu_P(\text{succ}(n))$. If $\mu_P(\text{succ}(n)) = \mu_P(n)$ since $\mu_P(n) < n$, then we are done by the induction hypothesis. Otherwise, either $\mu_P(\text{succ}(n)) = n$ and $P(n)$, or $\mu_P(\text{succ}(n)) = \text{succ}(n)$. In both cases we are done.

Also by induction on $n : \mathbb{N}$ and $d(n) : P(n) \text{I} \neg P(n)$ we show

$$P(m) \rightarrow \mu_P(n) \leq m, \text{ for all } m \in \mathbb{N}.$$ 

The base case $n \equiv 0$ holds since $\mu_P(0) = 0$. For the induction step, assume $P(m) \rightarrow \mu_P(n) \leq m$ for all $m$ (IH). Let $m : \mathbb{N}$ and assume $P(m)$. We have to prove $\mu_P(\text{succ}(n)) \leq m$. If $\mu_P(\text{succ}(n)) = \mu_P(n)$ we are done by IH. Otherwise we have $\mu_P(n) = n$ and $\mu_P(\text{succ}(n)) = \text{succ}(n)$ and $\neg P(n)$. Then $\mu_P(n) \leq m$ by IH, and $n \neq m$, so $\mu_P(\text{succ}(n)) \leq m$.

By contraposition we get from the previous result

$$\mu_P(n) = n \rightarrow \neg P(m), \text{ for all } m < n.$$ 

Note that there may not be any $n$ such that $P(n)$; the best we can do is to prove

$$P(n) \rightarrow P_{\min}(\mu_P(\text{succ}(n)))$$

by combining previous results. Assume $P(n)$. Then $\mu_P(\text{succ}(n)) \leq n < \text{succ}(n)$, so that $P(\mu_P(\text{succ}(n)))$. Moreover, $P(m) \rightarrow \mu_P(\text{succ}(n)) \leq m$ for all $m \in \mathbb{N}$. Hence $P_{\min}(\mu_P(\text{succ}(n)))$.

Since $\sum_{n : \mathbb{N}} P_{\min}(n)$ is a proposition, we obtain the required function by the induction principle for propositional truncation, Definition 2.16.1:

$$\min(P) : \prod_{n : \mathbb{N}} (P(n) \text{I} \neg P(n)) \rightarrow \left\| \sum_{n : \mathbb{N}} P(n) \right\| \rightarrow \sum_{n : \mathbb{N}} P_{\min}(n).$$

**Remark 2.23.5.** In the interest of readability, we do not always make the use of witnesses of decidability in computations explicit. A typical example is the case distinction on $\mu_P(n) < n$ in Construction 2.23.4 above. This remark applies to all sets and decidable relations on them. We shall immediately put this convention to good use in the proof of a form of the so-called Pigeonhole Principle (PHP).

**Lemma 2.23.6.** For all $N : \mathbb{N}$ and $f : \mathbb{N} \rightarrow \mathbb{N}$ such that $f(n) < N$ for all $n < N + 1$, there exist $m < n < N + 1$ such that $f(n) = f(m)$.

**Proof.** By induction on $N$. In the base case $N = 0$ there is nothing to do. For the induction case $N + 1$, assume the lemma proved for $N$ (induction hypothesis, IH, for all $f$). Let $f$ be such that $f(n) < N + 1$ for
all \( n < N + 2 \). The idea of the proof is to search for an \( n < N + 1 \) such that 

\[ P(n) \equiv (f(n) = N), \]

by computing \( \mu_p(N + 1) \) as in Construction 2.23.4.

If \( \mu_p(N + 1) = N + 1 \), that is, \( f(n) < N \) for all \( n < N + 1 \), then we are
done by IH. Assume \( \mu_p(N + 1) < N + 1 \), so \( f(\mu_p(N + 1)) = N \). If also
\( f(N + 1) = N \) then we are done. If \( f(N + 1) < N \), then we define \( g \) by
\( g(n) = f(N + 1) \) if \( f(n) = N \), and \( g(n) = f(n) \) otherwise. Then IH applies
to \( g \), and we get \( m < n < N + 1 \) with \( g(n) = g(m) \). If \( f(n) = f(m) \) we are
done. Otherwise, \( f(n), f(m) \) cannot both be smaller than \( N \), as
\( g(n) = g(m) \). In both remaining cases, \( f(n) = g(n) = g(m) = f(N + 1) \)
and \( f(N + 1) = g(n) = g(m) = f(m) \), we are done. \( \square \)

We can now rule out the existence of equivalences between finite sets of
different size.

**Corollary 2.23.7.** If \( m < n \), then \( (\sum_{k: \mathbb{N}} k < m) \not\equiv (\sum_{k: \mathbb{N}} k < n) \).

Another application of Construction 2.23.4 is a short proof of Euclidean
division.

**Lemma 2.23.8.** For all \( n, m : \mathbb{N} \) with \( m > 0 \) there exist unique \( q, r : \mathbb{N} \) such that
\( r < m \) and \( n = qm + r \).

**Proof.** Define \( P(k) \equiv (n \leq km) \). Since \( m > 0 \) we have \( P(n) \). Now set
\( k \equiv \mu_p(n) \) as in Construction 2.23.4. If \( n = km \) and we set \( q \equiv k \) and
\( r \equiv 0 \). If \( n < km \), then \( k > 0 \) and we set \( q \equiv k - 1 \). By minimality we
have \( qm < n < km \) and hence \( n = qm + r \) for some \( r < m \). \( \square \)

### 2.24 The type of finite sets

Recall from Section 2.12.1 the types False, True and Bool containing zero,
one and two elements, respectively. We now define generally the type of
\( n \) elements for any \( n : \mathbb{N} \).

**Definition 2.24.1.** For any type \( X \) define \( \text{succ}(X) \equiv X \sqcup \text{True} \). Define
inductively the type family \( \text{Fin}(n) \), for each \( n : \mathbb{N} \), by setting \( \text{Fin}(0) \equiv \emptyset \)
and \( \text{Fin}(\text{succ}(n)) \equiv \text{succ}(\text{Fin}(n)) \). The type \( \text{Fin}(n) \) is called the type with
\( n \) elements, and we denote its elements by \( 0, 1, \ldots, n - 1 \) rather than by
the corresponding expressions using \( \text{inl} \) and \( \text{inr} \).

We also define as abbreviation \( n \equiv \text{Fin}(n) \) for a natural number \( n \), so
\( 0 \equiv \text{Fin}(0), 1 \equiv \text{Fin}(1), 2 \equiv \text{Fin}(2), \) etc.

**Exercise 2.24.2.**

1. Denote in full the elements of \( 0, 1 \), and \( 2 \).
2. Construct an equivalence in \( \mathbb{1} \to \text{True} \) and one in \( \mathbb{2} \to \text{Bool} \).
3. Construct equivalences in \( n \to \sum_{k: \mathbb{N}} k < n \) for all \( n : \mathbb{N} \).
4. Show that \( m = n \) if we are given an element of type \( m \to n \). \( \square \)

**Definition 2.24.3.** Given a type \( X \), we define the proposition
\( \text{isFinSet}(X) \equiv \exists n : \mathbb{N} (X \to n) \)
to express that \( X \) is a finite set.\(^78\)

**Lemma 2.24.4.**

1. \( \sum_{n: \mathbb{N}} ||X \to n|| \) is a proposition, for all types \( X \).

\(^78\)When moving beyond sets, there
are two different ways in which a
type can be finite: an\( \textit{additive} \) way
and a\( \textit{multiplicative} \) way, but it would
take us too far afield to define these
notions here.
(2) The map that is the identity on first components is an equivalence 
\( (\Sigma X : U \sum_{n : \mathbb{N}} \| X \to n \|) \to \Sigma X : U \text{isFinSet}(X) \). 

Proof. (1) Assume \((n, p), (m, q) : \sum_{n : \mathbb{N}} \| X \to n \| \). Then \( q \circ p^{-1} : n \to m \), so \( n = m \) by Exercise 2.24.2. By Lemma 2.10.3, Definition 2.7.3 and the 
fact that the type of \( q \) is a proposition, it follows that \((n, p) = (m, q)\).

(2) Follows from \( \sum_{n : \mathbb{N}} \| X \to n \| = \| \sum_{n : \mathbb{N}} (X \to n) \| \), which is easily 
proved by giving functions in both directions and using the univalence 
axiom. \( \square \)

The lemma above remains true if \( X \) ranges over Set. If a set \( S \) is in the 
same component in Set\(^79\) as \( n \) we say that \( S \) has cardinality \( n \) or that the 
cardinality of \( S \) is \( n \).

**Definition 2.24.5.** The groupoid of finite sets is defined by

\[
\text{FinSet} \equiv \sum_{S : \text{Set}} \text{isFinSet}(S).
\]

For \( n : \mathbb{N} \), the groupoid of sets of cardinality \( n \) is defined by

\[
\text{FinSets}_n \equiv \sum_{S : \text{Set}} \| n = |S| \|.
\]

Observe that we have identifications in \( \text{FinSets}_0 \to \text{FinSets}_1 \to 1 \), and in 
\( \text{FinSet} \to \sum_{n : \mathbb{N}} \text{FinSets}_n \) by Lemma 2.24.4.

Note that being a finite set implies being a set, and hence we can 
identify \( \text{FinSet} \) with \( \sum_{X : U} \text{isFinSet}(X) \). Also, \( \text{FinSet} \) is the image of 
the map \( \text{Fin} : \mathbb{N} \to U \) from Definition 2.24.1, and is hence essentially 
\( U \)-small (for any universe \( U \)), by Principle 2.19.4, Item (P1) in Section 2.4, 
and our assumption that \( U_0 \) is the smallest universe.

### 2.25 Type families and maps

There is a natural equivalence between maps into a type \( A \) and type 
families parametrized by \( A \). The key idea is that the fibers of a map 
form a type family. We will elaborate this idea and some variations.

**Lemma 2.25.1.** Let \( A : U \) and \( B : A \to U \). Recall the function \( \text{fst} : (\sum_{a : A} B(a)) \to A \). Then \( e_a : B(a) \to \text{fst}^{-1}(a) \) defined by \( e_a(b) \equiv ((a, b), \text{refl}_a) \) is an 
equivalence, for all \( a : A \).

Proof. Note that \( \text{fst}(x, b) \equiv x \) and that \( a \to x \) does not depend on 
b. Hence \( \text{fst}^{-1}(a) \to \sum_{x : B(a)} \text{fst}^{-1}(a) \) via rearranging brackets. 
Applying Corollary 2.9.11 leads indeed to the equivalence \( e_a \). \( \square \)

**Lemma 2.25.2.** Let \( A, B : U \) and \( f : B \to A \). Then \( e : B \to \sum_{a : A} f^{-1}(a) \) 
defined by \( e(b) \equiv (f(b), b, \text{refl}_{f(b)}) \) is an equivalence.

Proof. Define \( e^{-1} : \sum_{a : A} f^{-1}(a) \to B \) by \( e^{-1}(a, b, p) \equiv b \), where \( p : a \to f(b) \). Then \( e^{-1}(e(b)) \equiv b \) for all \( b : B \). Let \( a : A, b : B \) and \( p : a \to f(b) \). Then \( e(e^{-1}(a, b, p)) \equiv (f(b), b, \text{refl}_{f(b)}) \). We have to identify \((a, b, p)\) with 
\((f(b), b, \text{refl}_{f(b)})\). We use \( p \) as identification of the first components (the 
horizontal identification \( p \) in the diagram in the margin), and \( \text{refl}_a \) as 
identification of the second components (whose type is constant). For 
the third component we use transport in the type family \( (_{-} \to f(b)) \)

\[
\begin{array}{ccc}
A & \to & B \\
\downarrow_{p} & \swarrow_{\text{refl}_{f(b)}} \\
f(b) & \to & f(b)
\end{array}
\]
and Exercise 2.14.4(3). Visualized in the diagram in the margin, we transport the horizontal identification \(p\) along the vertical one, also \(p\). The result of this transport can be identified with \(p \cdot p^{-1}\) and hence with \(\text{refl}_{f(b)}\), the diagonal identification in the diagram. Now apply Construction 2.9.9.

If \(f\) above is an injection, then \(\sum_{a:A} f^{-1}(a)\) is a subtype of \(A\), and \(B\) is a \(n\)-type if \(A\) is a \(n\)-type by Corollary 2.20.5.

**Lemma 2.25.3.** Let \(A\) be a type. Then

\[
\text{preim} : \sum_{B:A} (B \to A) \to (A \to \mathcal{U})
\]

given by \(\text{preim}(B, f)(a) \equiv f^{-1}(a)\) is an equivalence. An inverse equivalence is given by sending \(C : A \to \mathcal{U}\) to \(\sum_{a:A} C(a), \text{fst}\).

**Proof.** We apply Construction 2.9.9, and verify the two conditions. Let \(C : A \to \mathcal{U}\). We have to identify \(C\) with \(\text{preim}(\sum_{a:A} C(a), \text{fst})\). As \(\text{preim}(\sum_{a:A} C(a), \text{fst})(a) \equiv \text{fst}^{-1}(a)\), it suffices by function extensionality to identify the latter fiber with \(C(a)\), for all \(a : A\). This follows directly from Lemma 2.25.1 and the univalence axiom.

Let \(f : B \to A\). We have to identify \((\sum_{a:A} f^{-1}(a), \text{fst})\) with \((B, f)\). Using the univalence axiom, we get an identification \(\bar{e} : \sum_{a:A} f^{-1}(a) \simeq B\), where \(e\) is the equivalence from Lemma 2.25.2. Using Lemma 2.10.3, it remains to give an element of the type \(\text{fst} \bar{e}\).

As an auxiliary step we note that for any \(p : X \to Y\) and \(g : X \to A\), \(h : Y \to A\), the type \(g \equiv h \circ \bar{p}\) of paths over \(p\) can be identified with the type \(\bar{e} \equiv \bar{e} \circ \bar{f}\), since the two types are equal by definition for \(p \equiv \text{refl}_X\). Applying this here means that we must give an identification of \(\text{fst}\) with \(f \circ \bar{e}\). Hence it suffices to identify \(\text{fst}\) and \(f \circ e\), which follows by function extensionality from the definition of \(e\) in Lemma 2.25.2.

The above result can be generalized to situations with more properties and/or structure. Examples are to be found in Construction 2.25.6 below. We prepare by the following exercises.

**Exercise 2.25.4.** Let \(X\) and \(Y\) be types, \(p : Y \simeq X\) an identification, and \(T : X \to \mathcal{U}\) a type family. Construct an equivalence of type \(\sum_{x:X} T(x) \simeq \sum_{y:Y} T(p(y))\).

**Exercise 2.25.5.** Let \(S : \mathcal{U} \to \mathcal{U}\) and let \(X\) be a type. Construct an equivalence of type \((X \to \sum_{Y:U} S(Y)) \simeq \sum_{F:X \to \mathcal{U}} \prod_{x:X} S(F(x))\).

**Construction 2.25.6.** Let \(A\) be a type and \(S : \mathcal{U} \to \mathcal{U}\). Then we have equivalences of the following types:

1. \((A \to \sum_{B:U} S(B)) \simeq \sum_{B:U} \sum_{f:B \to A} \prod_{x:A} S(f^{-1}(a))\).
2. \((A \to \text{Prop}) \simeq \sum_{B:U} \sum_{f:B \to A} \prod_{x:A} \text{isProp}(f^{-1}(a))\).
3. \((A \to \text{Set}) \simeq \sum_{B:U} \sum_{f:U \to A} \prod_{x:A} \text{iset}(f^{-1}(a))\).
4. \((A \to \mathcal{U}) \simeq \sum_{B:U} \sum_{f:U \to A} \prod_{x:A} f^{-1}(a)\).

**Implementation of Construction 2.25.6.** (1) In view of Exercise 2.25.5, and rearranging sums on the right, it suffices to construct an equivalence of type \((\sum_{F:A \to \mathcal{U}} \prod_{x:A} S(F(x))) \simeq \sum_{(B,f)}: (\sum_{d:U} (B \to A)) \prod_{x:A} S(f^{-1}(a))\). Now
we can apply the equivalence constructed in Exercise 2.25.4 with $p$ the path induced by the equivalence preim from Lemma 2.25.3. Indeed, for $T(F) \equiv \prod_{a:A} S(F(a))$ we have $T(\text{preim}(B, f)) \equiv \prod_{a:A} S(f^{-1}(a))$.

For (2), use (1) with $S \equiv \text{isProp}$.

For (3), use (1) with $S \equiv \text{isSet}$.

For (4), use (1) with $S \equiv \text{id}_U$.

Since Prop is a set, we obtain the following corollary of Construction 2.25.6(2).

**Corollary 2.25.7.** Subtypes as in Definition 2.20.2 correspond to predicates $\text{Sub}_T$ is a set, for any type $T$.

### 2.26 Higher truncations

We’ve seen the propositional truncation in Section 2.16 and the set truncation in Section 2.22. As mentioned in Remark 2.22.17, it’s possible to define the latter in terms of the former by considering the propositional truncation of the identity types of a type $A$. In this section we want to generalize this to higher truncation levels and show how we can inductively define all the $n$-truncation operations using propositional truncation combined with the replacement principle, Principle 2.19.4, which is used to stay within a given universe.

**Construction 2.26.1.** For any integer $n \geq -1$ we have an $n$-truncation operation $\lVert \_ \rVert_n : \mathcal{U} \to \mathcal{U}$, along with unit maps $\lvert \_ \rvert_n : A \to \lVert A \rVert_n$, satisfying the following universal property.

For any $n$-type $B$, precomposition with $\lvert \_ \rvert_n$ induces an equivalence:

$$\lVert A \rVert_n \to B \cong (A \to B).$$

**Implementation of Construction 2.26.1.** We proceed by induction. For $n \equiv -1$, we have this from the higher inductive type definition, Definition 2.16.1, with element constructor $\lvert \_ \rvert : A \to \lVert A \rVert$.

To go from $n$ to $n + 1$, we fix a type $A : \mathcal{U}$ and consider the $n$-truncated identity type family

$$I_n : A \to \left( A \to \sum_{x : \mathcal{U}} \text{isType}(X) \right), \quad x \mapsto (y \mapsto \lVert x \cong y \rVert_n).$$

Let $\lVert A \rVert_{n+1} \equiv \text{im}(I_n)$ be the image of $I_n$, Definition 2.17.11, and let $\lvert \_ \rvert_{n+1} : A \to \lVert A \rVert_{n+1}$ be the map from the domain of $I_n$ to its image, $x \mapsto (I_n(x), (x : \text{refl}_{I_n(x)}))$ with $I_n(x) \equiv \lVert x \cong \_ \rVert_n$ as defined above.

Since the type of $n$-types is an $(n + 1)$-type, $\lVert A \rVert_{n+1}$ is an $(n + 1)$-type by Lemma 2.15.5. We also note that the map

$$(2.26.1) \quad \lVert x \cong y \rVert_n \cong (\lVert x \rVert_{n+1} \cong \lVert y \rVert_{n+1}),$$

induced by the universal property of $n$-truncation, is an equivalence. Indeed, the right-hand side is equivalent to

$$\prod_{z : A} (\lVert x \cong z \rVert_n \cong \lVert y \cong z \rVert_n),$$

and we get an inverse by going backwards along this equivalence at $\lvert \text{refl}_y \rvert_n : \lVert y \cong y \rVert_n$. 

To prove the universal property, let $B$ be any $(n+1)$-type and $g : A \to B$ any map.

It suffices to show that for any $z : \|A\|_{n+1}$, there is a contractible type of extensions $\sum_{y : B} (\_ \mapsto y) \overset{\sim}{\to} (\|\|_{n+1}(z) \mapsto B \,(g \circ \text{fst}))$, visualized by

$$
\begin{array}{ccc}
\|\|_{n+1}(z) & \xrightarrow{g \circ \text{fst}} & B, \\
\downarrow & & \\
\_ & \to & B,
\end{array}
$$

since then there’s a contractible type of extensions of $g$ to all of $\|A\|_{n+1}$. Since this is a proposition and $\|\|_{n+1}$ is surjective, it suffices to prove this for $z$ of the form $|x|_{n+1}$ with $x : A$. We need to show that the type

$$\prod_{x : A} \prod_{y : B} \prod_{x' : A} ((|x|_{n+1} \overset{\sim}{\to} |x'|_{n+1}) \to (y \overset{\sim}{\to} g(x')))$$

is contractible. By the equivalence above, we can rewrite this, first as

$$\prod_{x : A} \sum_{y : B} \prod_{x' : A} (|x| \overset{\sim}{\to} |x'|_{n} \to (y \overset{\sim}{\to} g(x')))$$

and then, since $y \overset{\sim}{\to} g(x')$ is an $n$-type, as

$$\prod_{x : A} \sum_{y : B} (x \overset{\sim}{\to} x') \to (y \overset{\sim}{\to} g(x'))).$$

Now we can contract away $x'$ and the identification $x \overset{\sim}{\to} x'$, so we’re left with

$$\prod_{x : A} \sum_{y : B} (y \overset{\sim}{\to} g(x'))),$$

which is indeed contractible.

Finally, we need to re-size $\|A\|_{n+1}$ to fit in the universe $U$ that $A$ came from. By (2.26.1), its identity types are essentially $U$-small by induction hypothesis, so again since $\|\|_{n+1}$ is a surjection from the $U$-small type $A$, the replacement principle, Principle 2.19.4, implies that $\|A\|_{n+1}$ is essentially $U$-small.

This construction is due to Rijke\textsuperscript{80}, see also the presentation in his book\textsuperscript{81}.

\subsection{2.27 Higher structure: stuff, structure, and properties}

Recall from Lemma 2.25.2 that any map $f : B \to A$ can be described as “projecting away” its fibers, by using the equivalence $e$:

$$
\begin{array}{ccc}
B & \xrightarrow{e} & \sum_{x : A} f^{-1}(a) \\
\xrightarrow{f} & & \xrightarrow{\text{fst}} A
\end{array}
$$

(2.27.1)

We say that $f$ forgets these fibers. If $A$ and $B$ are groupoids, these fibers are themselves groupoids, but it can happen that they are sets, propositions, or even contractible. Accordingly, we say that:

- $f$ forgets at most structure if all the fibers are sets;

80Rijke, \textit{The join construction}.

81Egbert Rijke. \textit{Introduction to Homotopy Type Theory}. Forthcoming book with CUP. Version from 06/02/22.

The precise formalization of the intuitive notions of “stuff”, “structure”, and “properties” was worked out in terms of category theory in Usenet discussions between John Baez, Toby Bartels, and James Dolan on sci.physics.research in 1998. It was clear that the simplest description was in terms of homotopy types, and hence it’s even simpler in type theory. See also Baez and Shulman\textsuperscript{82} for further discussion.

• \( f \) forgets at most properties if all the fibers are propositions;
• \( f \) forgets nothing if all the fibers are contractible.

Here, the structure and properties in question are on \( a \) or of \( a \), respectively, as captured by the fibers at \( a \), for each \( a : A \). Of course, a map forgets properties if and only if it’s an injection, and it forgets nothing if and only if it’s an equivalence.

Going in the other direction, we say that:
• \( f \) forgets at most \( n \)-structure if all the fibers are \( n \)-truncated. If \( n \geq 1 \), this is therefore a kind of higher structure.\(^3\)

Thus, an element of a groupoid is 1-structure (this is sometimes informally called stuff), while an element of a set is a structure, or 0-structure, while an proof of a proposition is a property, or \( (-1) \)-structure.

Looking at (2.27.1) another way, we see that to give an element \( b \) of \( B \) lying over a given element \( a : A \) amounts to specifying an element of \( f^{-1}(a) \), so we say that the elements of \( B \) are elements of \( A \) with extra \( n \)-structure, if the fibers \( f^{-1}(a) \) are \( n \)-truncated.

Refining the usual image and image factorization from Definition 2.17.11 and Exercise 2.17.12, using Lemma 2.25.2, we can factor \( f : B \to A \) through first its 0-image and then its usual \((−1)\)-image as follows:\(^4\)

\[
B \xrightarrow{\sim} \sum_{a : A} f^{-1}(a) \to \sum_{a : A} \|f^{-1}(a)\|_0 \to \sum_{a : A} \|f^{-1}(a)\|_{-1} \to A
\]

Here, the first map forgets pure higher structure, the second map forgets pure structure, while the last forgets at most properties (this is the inclusion of the usual image). Of course, each of these maps may happen to forget nothing at all. Saying that the second map forgets pure structure indicates that not only are the fibers sets, they are nonempty sets, so the structure in question exists, at least. Note also that the fibers of the first map are connected, which indicates that what is forgotten at this step, if anything, is pure higher structure.

**Example 2.27.1.** Let us look at some examples:

• The first projection \( \text{fst} : \text{FinSet} \times \text{FinSet} \to \text{FinSet} \) forgets 1-structure (stuff), namely the second set in the pair.

• The first projection \( \text{fst} : \text{FinSet}_A \to \text{FinSet} \) from the type of pointed finite sets to the type of finite sets forgets structure, namely the structure of a chosen point.

• The inclusion of the type of sets with cardinality \( n \), \( \text{FinSet}_n \), into the type of all finite sets, \( \text{FinSet} \), forgets properties, namely the property “having cardinality \( n \)”.

**Exercise 2.27.2.** Analyze more examples of maps between groupoids in terms of “what is forgotten”.

**Exercise 2.27.3.** Let \( [\_] : \|f^{-1}(a)\|_0 \to \|f^{-1}(a)\| \) be the map defined by the induction principle in Definition 2.22.4 from \( [\_] : f^{-1}(a) \to \|f^{-1}(a)\| \). In the refined image factorization above, the map for the second arrow maps any pair \( (a, x) \) with \( x : \|f^{-1}(a)\|_0 \) to the pair \( (a, [x]) \). For any \( p : \|f^{-1}(a)\| \), give an equivalence from the fiber of the latter map at \( (a, p) \) to \( \|f^{-1}(a)\|_0 \). What is forgotten by this map, and what is remembered? \( ^\dagger \)
3

The universal symmetry: the circle

An effective principle in mathematics is that when you want to study a certain phenomenon you should search for a single type that captures this phenomenon. Here are two examples:\(^1\)

1. The contractible type \(1\) has the property that given any type \(A\) a function \(1 \to A\) provides exactly the same information as picking an element in \(A\). For, an equivalence from \(A\) to \(1 \to A\) is provided by the function \(a \mapsto (x \mapsto a)\), see Exercise 2.9.18.

2. The type \(\text{Prop}\) of propositions has the property that given any type \(A\) a function \(A \to \text{Prop}\) provides exactly the same information as picking a subtype of \(A\), see Construction 2.25.6(2).

We are interested in symmetries, and so we should search for a type \(X\) which is so that given any type \(A\) the type of functions \(X \to A\) (or \(A \to X\), but that’s not what we’re going to do) picks out exactly the symmetries in \(A\). We will soon see that there is such a type: the circle\(^2\) which is built exactly so that this “universality with respect to symmetries” holds. It may be surprising to see how little it takes to define it; especially in hindsight when we eventually discover some of the many uses of the circle.

A symmetry in \(A\) is an identification \(p : a \rightsquigarrow a\) for some \(a : A\). Now, we can take any iteration of \(p\) (composing \(p\) with itself a number of times), and we can consider the inverse \(p^{-1}\) and its iterations. So, by giving one symmetry we give at the same time a lot of symmetries. For a particular \(p : a \rightsquigarrow a\) it may be that some of the iterations can be identified (in their type \(a \rightsquigarrow a\)). For instance, it may be that there is an identification of type \(p^2 \rightsquigarrow p^0\) (as in Exercise 2.13.3). Even more dramatically: if there is an identification of type \(p \rightsquigarrow \text{refl}_a\), then all the iterations of \(p\) can be identified with each other. However, in general we must be prepared that all the iterations \(p_n\) of \(p\) (for \(n\) positive, 0 and negative) are distinct. Hence, the circle must have a distinct symmetry for every integer. We would have enjoyed defining the integers this way, but being that ideological would be somewhat inefficient. Hence we give a more hands-on approach and define the circle and the integers separately. Thereafter we prove that the type of symmetries in the circle is equivalent to the set of integers.

3.1 The circle and its universal property

Propositional truncation from Section 2.16 was the first higher inductive type, that is, an inductive type with constructors both for elements and for

\(^1\) Notice that these have arrows pointing in different directions: In Item (1) we’re mapping out of \(1\), while in Item (2) we’re mapping in to \(\text{Prop}\).

\(^2\) We call this type the “circle” because it has many properties which are analogues, in our context, of properties of the topological circle \(\{(x, y) \in \mathbb{R}^2 | x^2 + y^2 = 1\}\). See Appendix B.3 for a discussion of the relationship between topological spaces and types. In the later chapters on geometry we’ll return to “real” geometrical circles.
identifications, we introduced. The circle is another example of a higher
inductive type, see Chapter 6 of the HoTT book\footnote{Univalent Foundations Program, Homotopy Type Theory: Univalent Foundations of Mathematics.} for more information.

**Definition 3.1.1.** The circle is a type $S^1: \mathcal{U}$ with an element (constructor) $\ast:S^1$ and an identification (constructor) $\bigcirc: \ast \to \ast$. For convenience and clarity the (higher) induction principle for $S^1$ is explained by first stating a recursion principle for $S^1$.

Let $A$ be a type. In order to define a function $f:S^1 \to A$, it suffices to
give an element $a$ of $A$ together with an identification $l$ of type $a \overset{\equiv}{\to} a$. The function $f$ defined by this data satisfies $f(*) \equiv a$ and the recursion
principle provides an identification of type $\text{apd}_f(\bigcirc) = l$.

Let $A(x)$ be a family of types parametrized by the variable $x:S^1$. The
induction principle of $S^1$ states that, in order to define a family of elements
of $A(x)$ parametrized by the variable $x:S^1$, it suffices to give an element
of $A(*)$ together with an identification $l$ of type $a \overset{\equiv}{\to} a$, see Fig. 3.1. The
function $f: \prod_{x:S^1} A(x)$ defined by this data satisfies $f(*) \equiv a$ and the
induction principle provides an identification of type $\text{apd}_f(\bigcirc) \overset{\equiv}{\to} l$.

Giving $a$ as above is referred to as ‘the base case’, and giving $l$ as ‘the
loop case’. Given this input data to define a function $f$ will often be
abbreviated by writing $f(*) \equiv a$ and $f(\bigcirc) \overset{\equiv}{\to} l$. Notice the use of $\overset{\equiv}{\to}$
in the second definition, instead of $\overset{\equiv}{\to}$. That signifies that $f(\bigcirc)$ and $l$
are not equal by definition, but rather, that an identification is given
between them, i.e., an element of type $f(\bigcirc) \overset{\equiv}{\to} l$ is given, or an element
of $\text{apd}_f(\bigcirc) \overset{\equiv}{\to} l$ is given, in the dependent case.

The following result states that any function from the circle exactly picks
out an element and a symmetry of that element. This is a “universal property”
of the circle.

**Theorem 3.1.2.** For all types $A$, the evaluation function

$ev_A : (S^1 \to A) \to \sum_{a:A} (a \overset{\equiv}{\to} a)$ defined by $ev_A(g) \equiv (g(*), g(\bigcirc))$

is an equivalence, with inverse $ve_A$ defined by the recursion principle of the circle.

**Proof.** Fix $A: \mathcal{U}$. We apply Construction 2.9.9. For all $a:A$ and $l:a \overset{\equiv}{\to} a$
we may construct an identification of type $\text{ev}(ve(a,l)) \overset{\equiv}{\to} (a,l)$ by the
recursion principle. It remains to construct identifications of type
$\text{ev}(\text{ev}(f)) \overset{\equiv}{\to} f$ for all $f:S^1 \to A$. Such constructions are provided by the
following more general result. Given $f,g:S^1 \to A$, $p:f(*) \overset{\equiv}{\to} g(*)$, and
$q:f(\bigcirc) \overset{p^{-1} \cdot g(\bigcirc) \cdot p}{\overset{\equiv}{\to}} p^{-1}$, we construct an identification
of type $f \overset{\equiv}{\to} g$, as follows. It suffices, by function extensionality, to construct
an element of type $P(x) \equiv (f(x) \overset{\equiv}{\to} g(x))$ for a variable $x:S^1$. This
we do by circle induction. For the base case we take $p$. The loop
case reduces to constructing an identification of type $\text{trp}_S(p) \overset{\equiv}{\to} p$, by
Definition 2.7.3. By Construction 2.14.3 we have an identification of type
$\text{trp}_S(p) \overset{\equiv}{\to} g(\bigcirc) \cdot p \cdot f(\bigcirc)^{-1}$. Using $q$ we construct an identification
of type $g(\bigcirc) \overset{p \cdot f(\bigcirc)^{-1}}{\overset{\equiv}{\to}} p \cdot f(\bigcirc) \cdot p^{-1}$, hence we may construct an identification
of type $(q \cdot p) \overset{\equiv}{\to} p$, by an easy calculation. Now apply Lemma 2.10.3,
and we have constructed a function of type $(\text{ev}(f) \overset{\equiv}{\to} \text{ev}(g)) \to (f \overset{\equiv}{\to} g)$.

Now we get an identification of type $\text{ev}(\text{ev}(f)) \overset{\equiv}{\to} f$, for we have an
identification of type $\text{ev}(\text{ev}(\text{ev}(f))) \overset{\equiv}{\to} (f(*), f(\bigcirc))$, and $(f(*), f(\bigcirc)) \equiv \text{ev}(f)$, with $p \equiv \text{refl}_{f(*)}$ and $q$ coming from the induction principle. }
**Corollary 3.1.3.** For any \( a : A \), the function
\[
\text{ev}_A^a : ((S^1, \star) \to (A, a)) \to (a \rightsquigarrow a)
\]
sending \((g, p)\) to \(p^{-1} \cdot g(\bigcirc) \cdot p\) is an equivalence.

**Proof.**\(^4\) Consider the following diagram (see Remark 2.15.10):
\[
\begin{array}{c}
(S^1 \to A) \\
\xrightarrow{\text{ev}_A} \sum_{a : A} ((S^1, \star) \to (A, a)) \\
\end{array}
\]
where the top map is an equivalence by Corollary 2.9.11, and the left map is an equivalence by Theorem 3.1.2. This diagram represents the identity type \(\text{ev}_A \rightsquigarrow (g \mapsto (g(\star), \text{refl}_{g(\star)}) \cdot g(\bigcirc) \cdot \text{refl}_{g(\star)}))\). An identification of this type is provided by function extensionality and Exercise 2.5.3. The result now follows from Lemma 2.9.16. \(\square\)

**Remark 3.1.4.** By almost the same argument as for Theorem 3.1.2 one can obtain the dependent universal property of the circle. Given a type family \(A : S^1 \to \mathcal{U}\), the dependent evaluation function, which also maps \(g \mapsto (g(\star), g(\bigcirc))\) but has type \((\prod_{x : S^1} A(x)) \to \sum_{a : A} (a \rightsquigarrow a)\), is an equivalence. (Compare the latter type to the type of \(\text{ev}_A\) in Theorem 3.1.2 and see Fig. 3.1.) \(\square\)

**Remark 3.1.5.** A function \(f : S^1 \to A\) is often called a loop in \(A\), the picture being that \(f\) throws \(\bigcirc \cdot \rightsquigarrow \star\) as a lasso in the type \(A\).

Using the equivalence in Corollary 3.1.3 and univalence, \(a \rightsquigarrow a\) is identified with the pointed functions from the circle, which allows for a very graphic interpretation of the symmetries of \(a\) in \(A\): they are traced out by a function \(f\) from the circle and can be seen as loops in the type \(A\) starting and ending at \(a\).\(^5\) \(\square\)

**Lemma 3.1.6.** The circle is connected.

**Proof.** We show \(\|\cdot \rightsquigarrow z\|\) for all \(z : S^1\) by circle induction as in Definition 3.1.1. For the base case we take \(\text{refl}.\mid : \|\star \rightsquigarrow \star\|.\) The loop case is immediate as \(\|\cdot \rightsquigarrow \star\|\) is a proposition. \(\square\)

In the proof above, the propositional truncation coming from the definition of connectedness is essential. If this truncation were removed we wouldn’t know what to do in the induction step (actually, having an element of type \(\prod_{x : S^1} (\star \rightsquigarrow z)\) contradicts the univalence axiom). This said, the family \(R : S^1 \to \mathcal{U}\) with \(R(z) \equiv (\star \rightsquigarrow z)\) is extremely important for other purposes. In Example 3.3.9, we will call \(R\) the “universal set bundle” of the circle, and it is the key tool in proving that the type of symmetries in the circle is a set that can be identified with the set of integers. Recall that we use the phrase “symmetries in the circle” to refer to the elements of \(\star \rightsquigarrow \star\), whereas we use the phrase “symmetries of the circle” to refer to the elements of \(S^1 \rightsquigarrow S^1\). The latter type is equivalent to \(S^1 \sqcup S^1\), as follows from Exercise 3.4.11 and Exercise 3.4.12.

In order to proceed, we should properly define the set of integers and explore the concept of set bundles.

\(^4\)This can also be done directly: The inverse to \(\text{ev}_A^a\) sends \(a \rightsquigarrow a\) to \((\text{ev}_A^a(a, l), \text{refl}_a)\). Try to verify this!

\(^5\)This is of course how we have been picturing loops the whole time.

\(^6\)Here we are using “the circle” to mean the pointed type \((S^1, \star)\). But it also turns out that the type \(\star \rightsquigarrow \star\) is equivalent to the type \(x \rightsquigarrow x\), for any \(x : S^1\).
3.2 The integers

We define the type of integers in one of the many possible ways.\footnote{Here are some of these alternatives:}

\begin{definition}
Let \( \mathbb{Z} \) be the higher inductive type with the following three constructors:

\begin{enumerate}
\item \( \iota_+: \mathbb{N} \to \mathbb{Z} \) for the nonnegative numbers, 0, 1, \ldots
\item \( \iota_-: \mathbb{N}^- \to \mathbb{Z} \) for the nonpositive numbers, \(-0, -1, \ldots
\item \( \text{zeq}: \iota_-(0) = \iota_+(0) \).
\end{enumerate}

Because we used the copy \( \mathbb{N}^- \) for the nonpositive numbers from Example 2.12.9, we can leave out the constructor symbols \( \iota_+ \) when the type is clear from context. Thus we have \ldots, -2, -1, 0, 1, 2, \ldots: \mathbb{Z} \) and \( \text{zeq} \): \(-0 \rightarrow \mathbb{Z} 0 \).

The type \( \mathbb{Z} \) comes with an induction principle: Let \( T(z) \) be a family of types parameterized by \( z : \mathbb{Z} \). In order to construct an element \( f(z) \) of \( T(z) \) for all \( z : \mathbb{Z} \), it suffices to give functions \( g \) and \( h \) such that \( g(n): T(\iota_+(n)) \) and \( h(n): T(\iota_-(m)) \) for all \( n : \mathbb{N}, m : \mathbb{N}^- \), together with \( q: h(0) \rightarrow \text{zeq} \rightarrow g(0) \).

Here \( g \) and \( h \) can be defined by induction on \( n : \mathbb{N}, m : \mathbb{N}^- \).

The resulting function \( f: \prod_{z : \mathbb{Z}} T(z) \) satisfies \( f(n) \equiv g(n) \) and \( f(-n) \equiv h(-m) \) for \( n : \mathbb{N}, \) and there is an (unnamed) element of \( \text{ap}_f(\text{zeq}) \) \( = q \).

Like the type \( \mathbb{N} \), the type \( \mathbb{Z} \) is a set with decidable equality and ordering relations.

One well-known self-equivalence is \textit{negation}, \(-: \mathbb{Z} \to \mathbb{Z}, \) inductively defined by setting \(-\iota_+(n) \equiv \iota_-(n), -\iota_-(m) \equiv \iota_+(m), \) \( \text{ap}_f(\text{zeq}) \equiv \text{zeq}^{-1} \).\footnote{Of course, giving \( h \) is the same as giving \( f': \prod_{z : \mathbb{N}} T(-n) \).}

Negation is its own inverse.

The \textit{successor} function \( s : \mathbb{Z} \to \mathbb{Z} \) is likewise defined inductively, setting \( s(n) \equiv \text{succ}(n), s(-0) \equiv 1, s(-\text{succ}(n)) \equiv -n, \) and \( \text{ap}_f(\text{zeq}) \equiv \text{refl} \).

The successor function \( s \) is an equivalence. It is instructive to depict iterating \( s \) in both directions as a doubly infinite sequence containing all integers:

\[
\cdots \longrightarrow -2 \longrightarrow -1 \longrightarrow -0 \longrightarrow 1 \longrightarrow 2 \longrightarrow \cdots
\]

The inverse \( s^{-1} \) of \( s \) is called the \textit{predecessor} function. We recall the \( n \)-fold iteration \( s^n \) defined earlier; the \( n \)-fold iteration of \( s^{-1} \) will be denoted by \( s^{-n} \). Since \( s^0 \equiv \text{id} \equiv s^{-0} \), this defines the iteration \( s^n \) for all \( z : \mathbb{Z} \).\footnote{Here we included the constructor symbols for clarity, but the definition allows us to use the negation symbol unadorned, because the following diagram is commutative by definition:}

\[\begin{array}{ccc}
\mathbb{N} & \longrightarrow & \mathbb{N}^- \\
\iota_- & \downarrow & \downarrow \iota_+ \\
\mathbb{Z} & \longrightarrow & \mathbb{Z}
\end{array}\]

\textit{Addition} of integers is now defined by iteration: \( z + y \equiv s^y(z) \). This extends \( + \) on the \( \iota_+ \)-image of \( \mathbb{N} \), see Exercise 3.2.2. From addition and \( -: \mathbb{Z} \to \mathbb{Z} \) one can define a \textit{subtraction} function setting \( z - y \equiv z + (-y) \).

Since addition and subtraction are mutually inverse, the function \( w \mapsto z + w \) is an equivalence, and we may iterate it to define \textit{multiplication}:

\[zy \equiv (w \mapsto z + w)y(0) \].

\begin{exercise}
Show that \( \iota_+(n + m) = \iota_+(n) + \iota_+(m) \) and \( \iota_+(nm) = \iota_+(n)\iota_+(m) \) for all \( n, m : \mathbb{N} \).
\end{exercise}

The ordering relations \( < \) and \( \leq \) on \( \mathbb{Z} \) are easily defined and shown to extend those on \( \mathbb{N} \).
Recall the induction principle for \( Z \) in Definition 3.2.1 above. Instead of defining \( g \) and \( h \) explicitly, we will often give \( f(0) \) directly, and define \( g' \) and \( h' \) such that \( g'(z):T(z) \to T(z+1) \) for all \( z:Z \) with \( z \geq 0 \), and \( h'(z):T(z) \to T(z-1) \) for all \( z:Z \) with \( z \leq 0 \). The function \( f \) thus defined satisfies \( f(-0) \equiv f(0), f(z+1) \equiv g'(z,f(z)) \) for all \( z \geq 0 \), and \( f(z-1) \equiv h'(z,f(z)) \) for all \( z \leq 0 \).

**Exercise 3.2.3.** Show that \( x + y = y + x \) and \( xy = yx \) for all \( x, y:Z \). \( \dashv \)

### 3.3 Set bundles

As mentioned earlier, it is possible to define the integers as the type \( \bullet \to \bullet \) of symmetries in the circle. Our investigation of \( \bullet \to \bullet \) will use the concept of set bundles. Since we are going to return to this concept several times, we take the time for a fuller treatment before we continue with proving the equivalence of \( \bullet \to \bullet \) and \( Z \).

**Definition 3.3.1.** A set bundle over a type \( B \) is a map \( f:A \to B \) such that for each \( b:B \) the preimage (fiber) \( f^{-1}(b) \) is a set. We say that a set bundle \( f:A \to B \) over \( B \)

- **connected** if \( A \) is connected,
- **finite** if all preimages are finite sets,
- **decidable** if all preimages are decidable sets.

If \( A \) and \( B \) are pointed types, a pointed set bundle is a pointed map \( f:A \to B \) such that, when forgetting the points, \( f_*:A_* \to B_* \) is a set bundle. Here it suffices that \( A \) is a pointed type.\(^{11}\)

We do not require the preimages of \( f_* \) to be pointed types. \( \dashv \)

With a formula, given a type \( B \), the type of set bundles over \( B \) is

\[
\text{SetBundle}(B) \equiv \sum_{A:U} \sum_{f:A \to B} \prod_{b:B} \text{isSet}(f^{-1}(b)),
\]

with variations according to the flavor.

Recall the equivalence in Construction 2.25.6(3) between the type \( B \to \text{Set} \) of sets of families of sets parametrized by elements of \( B \), and the type of set bundles over \( B \) given above. We shall frequently use this equivalence, even without explicit mention.

**Lemma 3.3.2.** For any type \( B \), \( \text{SetBundle}(B) \) is a groupoid.

**Proof.** By Lemma 2.22.1 we have that \( \text{Set} \) is a groupoid, and hence \( B \to \text{Set} \) is a groupoid by Lemma 2.15.5(1).

Moreover, by Corollary 2.20.5, all variations of set bundles in Definition 3.3.1 defined by a predicate are groupoids as well. This does not apply pointed set bundles: a point is extra structure, not just a property.

We should notice that the notion of a set bundle is just one step up from the notion of an injection (a map such that all the preimages are propositions – following the logic, injections perhaps ought to be called “proposition bundles”). The formulation we give is not the only one and for some purposes a formulation based on \( B \to \text{Set} \) is more convenient.

**Exercise 3.3.3.** Let \( A, B \) and \( C \) be types. Show:

\([^11\text{Given a pointed type } (A,a), \text{ a type } B \text{ and a map } f:A \to B, (f, \text{refl}_B):(A,a) \to (B,f(a)) \text{ is a pointed map. Indeed, the forgetful map } (\sum_{b:B}(A,a) \to (B,b)) \to (A \to B) \text{ is an equivalence by Corollary } 2.9.11.\)
(1) The (unique) map of type $A \to 1$ is a set bundle iff $A$ is a set;

(2) For any $b : B$, the map $x \mapsto b$ from $1$ to $B$ is a set bundle iff $b \mapsto b$ is a set;

(3) If $f : A \to B$ and $g : B \to C$ are set bundles, then $gf$ is a set bundle.

(4) If $f : A \to B$ and $g : B \to C$, and $g$ and $gf$ are set bundles, then $f$ is a set bundle. Hint: apply Corollary 2.17.9 to $ap_g : (b \mapsto f(a)) \to (g(b) \mapsto g(f(a)))$.

(5) If $A$ is connected, $a \mapsto A a$ is connected for some $a : A$, $B$ is a groupoid, and $f : A \to B$ is a set bundle, then $A$ is contractible. Hint: use Corollary 2.17.9 and Exercise 2.16.10.

(6) If $f : A \to B$ is a set bundle and $B$ is an $n$-type with $n \geq 0$, then $A$ is also an $n$-type.

Figure 3.2 visualizes two examples of set bundles over the circle. Consider the picture on the left first. If we let $b$ be the element on the circle marked at the bottom left hand side, then the preimage $f^{-1}(b)$ is marked by the two dots in $A$ straight above $b$, so that in this case each preimage contains two points (i.e., each preimage can be merely identified with $\text{Bool}$). However, $A$ is not the constant family, like $A'$ depicted on the right, since we have a string of identifications $A' \equiv \sum_z : S^1 \text{Bool} \rightarrow (S^1 \times \text{Bool}) \rightarrow (S^1 + S^1)$, and the latter type is not connected. Obviously something way more fascinating is going on.

Exercise 3.3.4. In this exercise you are asked to elaborate the difference between $A$ and $A'$ above. Let $c_{\text{Bool}} : (z \mapsto \text{Bool}) : S^1 \to \text{Set}$.

(1) This part is about $A'$. Show that $\sum_z : S^1 \text{Bool}$ is not connected. Give an element of the type $c_{\text{Bool}} \Rightarrow \text{veSet}(\text{Bool}, \text{refl}_{\text{Bool}})$.

(2) One can define $A$ by $A : \equiv \sum_{z : S^1} \text{veSet}(\text{Bool}, \text{twist})$. Show that $A$ is connected. Give an element of type $(c_{\text{Bool}} \Rightarrow \text{veSet}(\text{Bool}, \text{twist})) \Rightarrow \text{False}$. Hint: use Exercise 2.13.3 and Theorem 3.1.2.

Remark 3.3.5. It is possible to misunderstand what a “connected set bundle” is: the other interpretation “all the preimages are connected” would simply give us an equivalence (since connected sets are contractible), and this is not what is intended. (Equivalences are set bundles, but not necessarily connected set bundles and connected set bundles are not necessarily equivalences.) Likewise for the other qualifications; for instance, in a “finite set bundle” $f : A \to B$, all fibers are finite sets, but the type $A$ is usually not a finite set.
We trust the reader to keep our definitions in mind and not the other interpretations.

Remark 3.3.6. Set bundles are closely related to a concept from topology called “covering spaces” (or any variant of this concept, including Galois theory) and from algebra as locally constant sheaves (of sets). Either way, the concept is useful because it singles out the (sub)symmetries.

In this chapter, we focus on set bundles over the circle. We start by refining the notion of diagram introduced in Remark 2.15.10.

Remark 3.3.7. Consider the left diagram below, where $i_1, i_2$ are injections constituting $S$ as a subtype of $X$ and $T$ as a subtype of $Y$, respectively (see Definition 2.20.2). This diagram represents the identity type $f \circ i_1 \Rightarrow i_2 \circ g$. Since $i_2$ is an injection, the type $\sum_{g:S \rightarrow T}(f \circ i_1 \Rightarrow i_2 \circ g)$ is a proposition.

In the right diagram we depict the case in which $S$ is given by a predicate $P:X \rightarrow \text{Prop}$ and $T$ is given by a predicate $Q:Y \rightarrow \text{Prop}$, with the injections being first projections of the right type. We can now apply the universal property of subtypes Exercise 2.20.7 to $Q$ with $(f \circ \text{fst}):XP \rightarrow Y$ and get that the three propositions $\prod_{x:X}Q(f(\text{fst}(z)))$ and $\prod_{x:X}(P(x) \rightarrow Q(f(x)))$ and $\sum_{g:XP \rightarrow Q}(f \circ \text{fst} \Rightarrow \text{fst} \circ g)$ are logically equivalent. If these propositions hold, we say that $f$ respects the subtypes and we may call the diagram a subtype diagram.

If $q$ is a proof of $\prod_{x:X}(P(x) \rightarrow Q(f(x)))$, then we can uniquely define the function $g:XP \rightarrow YQ$, the one labelling the dashed arrow in the right diagram above, by $(x,p) \mapsto (f(x),q(x,p))$. The functions $f \circ \text{fst}$ and $\text{fst} \circ g$ are identified by reflexivity. We may call $g$ the function induced by $f$ on subtypes, and will also denote it by $f$.

Now consider the special case in which $f:X \rightarrow Y$ is an equivalence. If the inverse of $f$ also respects the subtypes, that is, if $\prod_{y:Y}Q(y) \rightarrow P(f^{-1}(y)))$, then the function that is induced by $f$ on the subtypes is also an equivalence. Moreover, the functions induced by $f$ and $f^{-1}$ are then each other’s inverses.

Theorem 3.3.8. In the diagram below, the equivalence $f$ in the second row is prem from Lemma 2.25.3, and the equivalence $g$ in the same row is defined by $g(S) \equiv (S(\ast), \text{trp}_{\text{id}_U}^{\text{id}_U})$ (Theorem 3.1.2 applied with $A \equiv U$, and Definition 2.13.1). Along the vertical arrows we have maps that forget the property that constitutes its domain as a subtype of the codomain, all modest variations of the first projection.

The statement of the theorem is now that the diagram below is the composite of subtype diagrams (see Remark 3.3.7) in which the induced functions $f$ and $g$ in the third row are equivalences as well.
\[ \sum_{X: \mathcal{U}}(X \to X) \]
\[ (\sum_{A: \mathcal{U}}(A \to S^1)) \xrightarrow{f} (S^1 \to \mathcal{U}) \xrightarrow{g} \sum_{X: \mathcal{U}}(X \xrightarrow{\simeq} X) \]
\[ \text{SetBundle}(S^1) \xrightarrow{f} (S^1 \to \text{Set}) \xrightarrow{g} \sum_{X: \text{Set}}(X \xrightarrow{\simeq} X) \]

**Proof.** We prove first that preim respects the subtypes. Let \( A: \mathcal{U} \) and \( h: S^1 \to A \) such that \((A, h)\) is a set bundle. This means that \( h^{-1}(a) \) is a set, for any \( a: A \). Since \( \text{preim}(A, h)(a) \equiv h^{-1}(a) \), we immediately get that \( \text{preim}(A, h): S^1 \to \text{Set} \). In order to prove that \( \text{preim}^{-1} \) also respects the subtypes one simply reverses this argument.

Next we prove that \( g \) respects the subtypes. Let \( S: S^1 \to \mathcal{U} \) be such that \( S(z) \) is a set for all \( z: S^1 \). This means in particular that \( S(\cdot) \) is a set. Since \( g(S) \equiv (S(\cdot), \text{trp}_{S(\cdot)}) \), we are done. In order to prove that \( g^{-1} \) also respects the subtypes we reason as follows. Let \( X: \mathcal{U} \) and \( h: X \xrightarrow{\simeq} X \) be given. Assume that \( X \) is a set. We have \( g^{-1}(X, h) \equiv \text{vgl}(X, \bar{h}) \), see Theorem 3.1.2 and Principle 2.13.2. Now, since \( X \equiv \text{vgl}(X, \bar{h})(\cdot) \) is a set and \( S^1 \) is connected, we have \( g^{-1}(X, h): S^1 \to \text{Set} \) and we are done.

Note that the left subtype diagram is fully general: it also holds when we replace \( S^1 \) by any type \( B \). This is not true for the right subtype diagram. \( \square \)

In slogan form: A set bundle over the circle is a set with a permutation of its elements. The fiber over \( \cdot: S^1 \) gives the set, and transporting along \( \bigcup \) gives the permutation.

**Example 3.3.9.** A simple yet important example of a set bundle over a groupoid \( B \) with an element \( b_0 \) is given by the family of identity types \( \text{Id}_{b_0}(b) \equiv (b_0 \to b) \) parameterized by \( b: B \). These identity types are indeed sets since \( B \) is a groupoid. The alternative form of this (pointed) set bundle is the map \( \text{fst} : \sum_{b: f}(b_0 \xrightarrow{\simeq} b) \to B \), the domain canonically pointed at \( (b_0, \text{refl}_{b_0}) \), and with \( \text{refl}_{b_0} \) as the pointing path of \( \text{fst} \).

In the above example, the reader may have noticed that, by Lemma 2.9.2, \( \sum_{b: B}(b_0 \xrightarrow{\simeq} b) \) is contractible. Hence yet another form of this set bundle is the constant map \( \text{cst}_{b_0} : 1 \to B \), also with pointing path \( \text{refl}_{b_0} \). What is special about these examples is captured by the following definition and ensuing lemma.

**Definition 3.3.10.** Let \( A \) and \( B \) be pointed sets and \( f: A \to B \) a pointed set bundle. We call \( f \) **universal** if for every pointed set bundle \( g: C \to B \) there is a unique \( h: A \to C \) with \( f \xrightarrow{\simeq} gh \), that is, if the following type is contractible:

\[ \sum_{h: A \to C} f \xrightarrow{\simeq} A \to B \quad gh. \]

In the above definition we get that \( h: A \to C \) is a set bundle as well by Exercise 3.3.3(4). The examples preceding Definition 3.3.10 are indeed universal set bundles according to the following lemma.

**Lemma 3.3.11.** Let \((A, a_0)\) be a pointed type, \((B, b_0)\) a pointed groupoid, and \( f: (A, a_0) \to (B, b_0) \) a pointed set bundle. Then \( f \) is universal if and only if \( A \) is contractible.
Proof. Let conditions be as above and assume \( A \) is contractible. Let \((C, c_0)\) be a pointed type and \( g :(C, c_0) \to (B, b_0) \) a set bundle. Let \( f_0 : b_0 \to f(a_0) \) and \( g_0 : b_0 \to g(c_0) \) be the respective pointing paths. Define \( h : (A, a_0) \to (C, c_0) \) by \( a \mapsto c_0 \) with pointing path \( \text{refl} \). Clearly \( g_0 f_0^{-1} : f(a_0) \to g(h(a_0)) \equiv g(c_0) \), which yields an identification of \( f(a) \) and \( g(h(a)) \) for all \( a : A \) as \( A \) is contractible. Apply now function extensionality Principle 2.9.17 to get an identification of type \( f \equiv_{A \to B} g \). The pointing path of \( g \) is also \( g_0 : b_0 \to g(c_0) \). We get an identification of type \( (f, f_0) \equiv_{A \to B} (g, g_0) \) since \( g_0 = (g_0 f_0^{-1}) f_0 \). The type \((A, a_0) \to (C, c_0)\) is contractible since \( A \) is contractible, yielding that \( h \) is unique.

For the other direction of the lemma we use a reasoning pattern that is typical for universality. Assume that \( f \) is universal. As shown above, \( \text{cst}_{b_0} : 1 \to (B, b_0) \) is also universal. Hence we have maps \( h \) and \( h' \) and identifications of all identity types represented in the following diagram, simplified by ignoring the points:

![Diagram](https://via.placeholder.com/150)

Using the universality of \( f \), we can identify \( h'h \) with \( \text{id}_A \). Using the universality of \( \text{cst}_{b_0} \), we can identify \( hh' \) with \( \text{id}_1 \). Now Construction 2.9.9 yields an equivalence between \( 1 \) and \( A \), implying that \( A \) is contractible. \( \square \)

A particularly important example of a pointed set bundle is the following.

**Definition 3.3.12.** Recall the set of integers \( \mathbb{Z} \) from Definition 3.2.1, with its successor function \( s : \mathbb{Z} \to \mathbb{Z} \) being an equivalence. The set bundle \( R : S^1 \to \mathcal{U} \) is defined by the recursion principle of the circle from Definition 3.1.1 by putting \( R(*) \equiv \mathbb{Z} \) and \( R(\cup) : = \mathbb{Z} \). This is indeed a set bundle since \( S^1 \) is connected, so that \( R(x) \) is a set for all \( x : S^1 \). We also write \( R : S^1 \to \text{Set} \). Recall \( \text{Tot}(R) \equiv \sum_{z : S^1} R(z) \) and point \( \text{Tot}(R) \) at \((*, 0)\). Now define

\[
\exp : \equiv\text{fst} : \text{Tot}(R) \to S^1, \text{ with pointing path refl.}
\]

We call \( \exp \) the **exponential set bundle over the circle**.

**Remark 3.3.13.** The reason for the name “exponential” comes from the following visualization. If \( x \) is a real number, then the complex exponentiation \( e^{2\pi i x} = \cos(2\pi x) + i \sin(2\pi x) \) has absolute value 1 and so defines a continuous function to the unit circle \( \{ (x, y) : \mathbb{R}^2 \mid x^2 + y^2 = 1 \} \), where we have identified \( \mathbb{R}^2 \) with the complex numbers. Choosing any point \( z \) on the unit circle, we see that the preimage of \( z \) under the exponential function is a shifted copy of the integers inside the reals. \(^{14}\)

This connection between the integers and the unit circle is precisely captured in a form that we can take further by studying the set bundle \( \exp : \text{Tot}(R) \to S^1 \).

In the next section we will see that the exponential set bundle of the circle is in fact universal. We’ll continue the general study of set bundles

14Homotopy types have to wait until Appendix B.3
in Section 4.7 and indeed throughout the book. For now, we’ll focus our attention on the circle and set bundles over it.

### 3.4 The symmetries in the circle

With the set \( Z \) of integers defined as in Section 3.2, we will now construct an equivalence between \( Z \) and the type \( \ast \to \text{Sym} \ast \), and that under this equivalence \( 0 : Z \) corresponds to refl.: \( \ast \to \ast \), and 1 to \( \cup \), and \(-1\) to \( \cup^{-1} \). More generally, the successor \( s : Z \to Z \) corresponds to composition with \( \cup \), while the predecessor \( s^{-1} \) corresponds to composition with \( \cup^{-1} \).

The first step is to identify the exponential set bundle Definition 3.3.12 with the universal set bundle in Example 3.3.9, i.e., identify the type family

\[
R : S^1 \to \mathcal{U}, \quad R(\ast) \equiv Z, \ R(\cup) \equiv \bar{s}
\]

with the family

\[
P : S^1 \to \mathcal{U}, \quad P(z) \equiv (\ast \to z).
\]

What does it mean to identify the families \( P \) and \( R \)? Type families are a special case of functions. Function extensionality reduces the question to the pointwise identification of \( P \) and \( R \) as functions. Using univalence, it suffices to give an equivalence from \( P(z) \) to \( R(z) \) for every \( z : S^1 \), that is, recalling Definition 2.14.1, giving a (fiberwise) equivalence \( f : P \to R \). We will use Construction 2.9.9, so will also define \( g : R \to P \).

**Remark 3.4.1.** We recall Construction 2.14.2 defining how transport behaves in families of function types. Given a type \( A \) and two type families \( P, Q : A \to \mathcal{U} \), transport along \( p : a \to a' \) of \( h : P(a) \to Q(a) \) can be identified with the function \( \text{tr}_{P(a)}^Q \circ h \circ \text{tr}_{P(a')}^P \) of type \( P(a') \to Q(a') \). As a simplification we could use the notation \( \circ \) introduced after Principle 2.13.2 for the transport functions. However, we now take the further step of allowing univalence to be completely transparent, that is, leaving out both \( \circ \) and \( \to \) when no confusion can occur. Here this means that the picture for the transport of \( h \) becomes:

\[
\begin{array}{ccc}
  a & \xrightarrow{P(a)} & Q(a) \\
  a' & \xrightarrow{P(a')} & Q(a') \\
end{array}
\]

In, for example, the definition of the exponential set bundle \( R \) above, this means that we may denote \( R(\cup) \) as \( \bar{s} \) instead of \( s \), and may write \( R(\cup)(0) = 1 \).

If \( A \) is \( S^1 \), then the induction principle for the circle says that giving an \( h(z) : P(z) \to Q(z) \) for all \( z : S^1 \) is the same as specifying an element \( h(\ast) : P(\ast) \to Q(\ast) \) and, using Definition 2.7.3 and Remark 3.4.1, an identification \( h(\cup) : Q(\cup) \circ h(\ast) \to h(\ast) \), see the following diagram:

\[
\begin{array}{ccc}
P(\ast) & \xrightarrow{h(\ast)} & Q(\ast) \\
\downarrow{P(\cup)} & & \downarrow{Q(\cup)} \\
P(\ast) & \xrightarrow{h(\ast)} & Q(\ast)
\end{array}
\]
If \( P, Q \) are families of sets, then \( h(U) \) is a proof that this diagram commutes.

We now define \( f : P \to R \) and \( g : R \to P \), that will turn out to give inverse equivalences between \( P(z) \) and \( R(z) \), for each \( z : S^1 \).

**Definition 3.4.2.** The function \( f : \prod_{z : S^1} (P(z) \to R(z)) \) is defined by \( f(z)(p) \equiv R(p)(0) \).

In Figure 3.3, the function \( f(\star)(p) \) above has been visualised for \( p \equiv U^n \), \( n \equiv \pm 2, \pm 1, 0, 1, 2 \).

**Lemma 3.4.3.** For \( f \) as in Definition 3.4.2 we have \( f(\star)(U^n) = n \) for all \( n : Z \).

**Proof.** First consider positive \( n : N \) and apply induction. In the base case \( n = 0 \) we have \( f(\star)(U^0) \equiv f(\text{refl.}) \equiv \text{trp}_{\text{refl.}}(0) \equiv 0 \). For \( n \equiv s(m) \) with \( m : N \) we have

\[
\begin{align*}
  f(\star)(U^{s(m)}) & \equiv R(U^{s(m)})(0) \\
                        & = R(U)(U^m)(0) \\
                        & = R(U)(f(\star)(U^m)) \\
                        & = s(f(\star)(U^m)) = s(m) \quad \text{by the induction hypothesis.}
\end{align*}
\]

This completes the induction step for positive \( n \). For negative \( n \) the proof is similar. □

In the definition of the second map, take into account that \( R(\star) \equiv Z \) and \( P(\star) \equiv (\star \sim \star) \).

**Definition 3.4.4.** The function \( g : \prod_{z : S^1} (R(z) \to P(z)) \) is defined by circle induction. We first define \( g(\star) \equiv (n \mapsto U^n) : Z \to (\star \to \star) \).

Then, using Remark 3.4.1, the type \( g(U) \) should be

\[
P(U) \equiv g(\star) R(U)^{-1} \Rightarrow g(\star).
\]

By definition, \( R(U) \) is \( s \). Using Exercise 2.14.4(2) we can identify \( P(\star) \) with composition with \( U \). The element \( g(U) \) is obtained by function extensionality and a simple calculation, using the identification of \( U U^{n-1} \) and \( U^n \) for any \( n : Z \).

**Theorem 3.4.5.** For every \( z : S^1 \), the functions \( f(\star) \) defined in Definition 3.4.2 and \( g(\star) \) in Definition 3.4.4 are inverse equivalences between \( P(z) \) and \( R(z) \).  

**Proof.** We apply Construction 2.9.9 and verify the two conditions. First, we need to give elements \( H(z, p) : g(z)(f(z)(p)) \Rightarrow p \) for all \( z : S^1 \) and \( p : P(z) \equiv (\star \sim \star) z \). By induction on \( p : \star \sim \star z \) it suffices to set \( H(\star, \text{refl.}) \equiv \text{refl.} \) since \( g(\star)(f(\star)(\text{refl.})) \equiv g(\star)(0) \equiv \text{refl.} \).

Secondly, we need to give elements \( G(z)(n) : f(z)(g(z)(n)) = n \) for all \( z : S^1 \) and \( n : R(z) \). By circle induction it suffices to define \( G(\star) \) and \( G(U) \), but the type of \( G(\star) \) is a proposition (as \( Z \) is a set), so the information for \( G(U) \) is redundant. Hence, it suffices to show that \( f(\star)(g(\star)(n))) \equiv f(\star)(U^n) = n \) for all \( n : Z \). This follows from Lemma 3.4.3. □
Corollary 3.4.6. The circle $S^1$ is a groupoid, and the function

$$\bigcup^\sim: Z \to (\ast \xrightarrow{\sim} S^1 \ast)$$

sending $n$ to $\bigcup^n$ is an equivalence.

Proof. For any $z:S^1$, the type $\text{P}(z) \equiv (\ast \xrightarrow{\sim} S^1 \ast)$ is a set since $R(z)$ is a set and $f(z): \text{P}(z) \to R(z)$ an equivalence. Since the circle is connected and being a set is a proposition, it follows that $y \xrightarrow{\sim} z$ is a set, for any $y, z:S^1$. Hence $S^1$ is a groupoid. By Definition 3.4.4, $\bigcup^{-} \equiv g(\ast)$ is an equivalence.  

Recall the definition of universal set bundle from Definition 3.3.10. Now that we know that the circle is a groupoid we can harvest the following results.

Corollary 3.4.7. The set bundle $P$, from Example 3.3.9 is universal. The exponential set bundle $\text{Exp}$ from Definition 3.3.12 is universal.

Proof. By Lemma 3.3.11 and Theorem 3.4.5. 

Definition 3.4.8. The inverse equivalence $f(\ast)$ of $g(\ast) \equiv \bigcup^{-} \equiv (n \mapsto \bigcup^n)$ is called the winding number function $\text{wdg}:(\ast \xrightarrow{\sim} \ast) \to Z$. 

The following lemma is a simple example of a technique called delooping, which we will further elaborate in Section 4.10.

Lemma 3.4.9. Let $A$ be a connected type and $a : A$ an element. Assume we have an equivalence $e : (\ast \xrightarrow{\sim} \ast) \to (a \xrightarrow{\sim} a)$ of symmetries such that $e(\text{refl}) \equiv \text{refl}$ and $e(p \cdot q) \equiv e(p) \cdot e(q)$, for all $p, q : (\ast \xrightarrow{\sim} \ast)$. Then $\tilde{e} : S^1 \to A$ defined by circle recursion by setting $\tilde{e}(\ast) \equiv a$ and $\tilde{e}(\bigcup) \equiv e(\bigcup)$ is an equivalence.

Proof. We have $a \cdot \tilde{e} \equiv \tilde{e}$ since they produce equal values when applied to $\bigcup^n$, for all $n : Z$. Now use that $A$ and $S^1$ are connected and apply Corollary 2.17.9(2).  

Exercise 3.4.10. Generalizing Definition 3.4.8, of winding numbers, use circle induction to define, for any point $x : S^1$ of the circle an equivalence, $\text{wdg}_x : (x \xrightarrow{\sim} x) \to Z$. (You’ll need commutativity of addition in $Z$.) Conclude from Lemma 3.4.9 that we have equivalences $f_x : S^1 \to S^1$ with $f_x(\ast) \equiv x$, for each $x : S^1$. 

Exercise 3.4.11. Let $-\text{id}_{S^1} : S^1 \to S^1$ be defined by $-\text{id}_{S^1}(\ast) \equiv \ast$ and $-\text{id}_{S^1}(\bigcup) \equiv \bigcup^{-1}$. Show the $-\text{id}_{S^1}$ and $\text{id}_{S^1}$ are not in the same component of $S^1 \to S^1$. Prove the following proposition: 

$$\prod_{t : S^1 \to S^1} \|\text{id}_{S^1} \xrightarrow{\sim} t\| \|\text{id}_{S^1} \xrightarrow{\sim} t\|.\quad \square$$

Exercise 3.4.12. For any $f : S^1 \to S^1$, give an equivalence from $S^1$ to $(S^1 \to S^1)_{(f)}$, that is, from $S^1$ to the component of $S^1 \to S^1$ at $f$. Hint: use Lemma 3.4.9. 

We note in passing that combining the above two exercises yields an equivalence from $(S^1 \xrightarrow{\sim} S^1)$ to $(S^1 \| S^1)$, that is, a characterization of the symmetries of the cycle (in contrast to the title of this Section 3.4).
3.5  A reinterpretation of the circle

In this section we return to the equivalences in Theorem 3.3.8. We’ll use these to get a different perspective on the circle, which highlights it as a type classifying very simple symmetries, namely sets with permutations. We have already seen one example in Definition 3.3.12, namely the set $\mathbb{Z}$ of integers together with the successor function $s: \mathbb{Z} \rightarrow \mathbb{Z}$, defining the exponential set bundle $exp$. By Corollary 3.4.7, $exp$ and its friends $\text{P}: S^1 \rightarrow \text{Set}$ and $\text{cst}: 1 \rightarrow S^1$ are appearances of the universal set bundle over the circle.

The importance of $exp$ will become apparent when we eventually explain that the circle is equivalent to the connected component of $(Z,s)$ in the type $\sum_{X:U}(X \rightarrow X)$.

Recall from Theorem 3.3.8 the equivalence

$$g.f: \text{SetBundle}(S^1) \simeq \sum_{X: \text{Set}} (X \rightarrow X).$$

When restricting to corresponding connected components, we get equivalences between these. So to understand the components of $\text{SetBundle}(S^1)$ it suffices to understand the components of $\sum_{X: \text{Set}} (X \rightarrow X)$, which correspond to components of $\sum_{X:U} (X \rightarrow X)$ at pairs $(X,t)$, where $X$ is a set with a permutation $t$.

We are particularly interested in understanding the symmetries in these components, so before we prove that the circle is equivalent to the component containing $(Z,s)$, let us investigate the equalities in the type $\sum_{X:U} (X \rightarrow X)$ a bit further.

Define the type family $D$ by $D(X) \equiv (X \rightarrow X)$ for all $X:U$. Recall that, given $X,Y:U$ and $t: X \rightarrow X$ and $u: Y \rightarrow Y$, Lemma 2.10.3 and Definition 2.7.3 give an equivalence between the identity type $(X,t) \rightarrow (Y,u)$ and type of pairs consisting of a $p: X \rightarrow Y$ and an identification of type $\text{trp}^D_p(t) \rightarrow u$. The transport on the left is precisely the special case described after Construction 2.14.2 (see diagram in the margin), so that the latter identity type is equivalent to $\tilde{p} \circ t \circ \tilde{p}^{-1} \rightarrow u$. If $p \equiv \tilde{e}$ for an equivalence $e: X \rightarrow Y$, this is equivalent to $e \circ t \rightarrow u \circ e$, or $et \rightarrow ue$ for short. In total, we have an equivalence between the identity type $(X,t) \rightarrow (Y,u)$ and the sum type (see diagram in the margin)

$$\sum_{e: X \rightarrow Y} et \simeq_{X \rightarrow Y} ue.$$

These types are sets whenever $X$ and $Y$ are, and then we may write $et = ue$.

In particular, given a set $X$ with a permutation $t$, we have an equivalence from $(Z,s) \rightarrow (X,t)$ to $\sum_{Z \rightarrow X} es = te$. See Fig. 3.4 for an illustration. This equivalence is transparent in the sense that we never denote it. For example, any power $s^n$ of $s$ itself gives a symmetry $(s^n, p): (Z,s) \rightarrow (Z,s)$, where $p$ is a proof of $s^0 \rightarrow s s^n$.

Remark 3.5.1. The type $s^n s = s s^n$ in the paragraph above is a proposition. Since all elements of a proposition are equal, it is often not necessary to name such elements explicitly. If the proposition in question is clear from the context, we may use ! as a default name of its elements. Be warned that different occurrences of ! may refer to elements of different propositions. In cases where the element of a proposition is not of

---

16 The elements of this connected component can be thought of as infinite cycles: sets $X$ with a successor function $t: X \rightarrow X$ such that $(X,t)$ can be merely identified with $(Z,s)$. That is, $(X,t)$ looks exactly like $(Z,s)$, but we don’t know which element of $X$ is “zero”:

![Diagram](image)

17 Given a set $X$ with a permutation $t$, we may coerce and view $(X,t)$ as an element of $\sum_{X:U} (X \rightarrow X)$. Then, for any $(Y,u)$ in the same connected component of $\sum_{X:U} (X \rightarrow X)$ as $(X,t)$, we have that $Y$ also is a set and $u$ also a permutation of $Y$.

---

Figure 3.4: An identification of two infinite cycles. The equivalence $e: Z \rightarrow X$ is marked in blue.
interest (beyond its mere existence), we may even just ignore it. For example, again in the paragraph above, we may ignore \( p \) and consider \( s^n \) as a symmetry of \((Z, s)\). (Note that we did already coerce the function \( s^n \) to the equivalence.)

The following property jumps out at us when we contemplate Fig. 3.4: the equivalence \( e \) is uniquely determined by the element \( e(0) : X \). More precisely:

**Lemma 3.5.2.** For every \((X, t)\) in the component of \( \sum_{X : \mathcal{U}} (X \to X) \) containing \((Z, s)\), the function

\[
ev_0 : ((Z, s) \xrightarrow{\sim} (X, t)) \to X \text{ defined by } \ev_0(e, t) \equiv e(0)
\]

is an equivalence.

**Proof.** We’ll prove that every fiber of \( \ev_0 \) is contractible. Given \( x_0 : X \) we must determine a unique equivalence \( e : Z \to X \) such that \( es = 1e \) and \( e(0) = x_0 \). Induction on \( n : Z \) (positive and negative \( n \) separately) shows that for such an \( e \), we have \( e(n) = t^n(x_0) \) for all \( n : Z \). It remains to prove that \( n \mapsto t^n(x_0) \) is an equivalence, for every \( x_0 : Z \). Since we are proving a proposition, and we are assuming \((X, t)\) is in the component of \((Z, s)\), it suffices to prove it for \((X, t) \equiv (Z, s)\). Clearly, for any \( x_0, n : Z \), we have \( s^n(x_0) = n + x_0 \), and the map \( n \mapsto n + x_0 \) is an equivalence, with inverse \( n \mapsto n - x_0 \).

In particular, \( \ev_0 : ((Z, s) \xrightarrow{\sim} (Z, s)) \to Z \) is an equivalence, mapping \( s^n \) to \( n \) for all \( n : Z \). Cf. \( \text{wdg} : (\bullet \xrightarrow{\sim} \cdot) \to Z \) from Definition 3.4.8.

**Definition 3.5.3.** Let \( \inf\text{Cyc} \) be the component of \( \sum_{X : \mathcal{U}} (X \to X) \) containing \((Z, s)\). Elements of \( \inf\text{Cyc} \) are called *infinite cycles*.\(^\dagger\)

Define by circle induction

\[
c : S^1 \to \inf\text{Cyc} \text{ setting } c(\bullet) \equiv (Z, s)
\]

and \( c(\cup) : c(\bullet) \xrightarrow{\sim} c(\bullet) \) given by the predecessor equivalence \( s^{-1} : (Z \to Z) \) and the trivial proof of the proposition \( s^{-1} s = s s^{-1} \).

As explained in Remark 3.5.1, we often leave out the propositional data pertaining to \( \inf\text{Cyc} \) (and other subtypes) from the notation.

The main result of this section is Theorem 3.5.6 below, stating that the function \( c \) from Definition 3.5.3 is an equivalence. Since it’s such a crucial result, we are going to give two proofs. Each proof illuminates a different aspect and gives methods that will be used later.

For the first, we return to the equivalences of Theorem 3.3.8. As said above, these restrict to equivalences between corresponding components. In particular, \( \ev_\mathcal{U} : (S^1 \to \mathcal{U}) \xrightarrow{\sim} \sum_{X : \mathcal{U}} (X \xrightarrow{\sim} X) \) maps the type family \( P \) to the pair \((\bullet \xrightarrow{\sim} \cdot, \cup \_\_\_), \) which can be identified with \((Z, s)\) through Corollary 3.4.6. Hence, \( \ev_\mathcal{U} \) restricts to an equivalence between the connected component of \( P \) in \( S^1 \to \mathcal{U} \) and the connected component of \((Z, s)\) in \( \sum_{X : \mathcal{U}} (X \xrightarrow{\sim} X) \).

Recall the constant maps \( \text{cst}_z : (1 \to S^1) \) for \( z : S^1 \). The equivalence preimage \( \text{cst} \) maps \( z : S^1 \mapsto \sum_{X : \mathcal{U}} (x \xrightarrow{\sim} \cdot) \) which can be identified with

\[\text{P}(\bullet)\]

\[S^1 \cup \]

\[\text{fig:plus-minus-one}\]

\(\dagger\)See also Definition 3.6.3 below for general cycles.
P. Now consider the following diagram:

\[
\text{SetBundle}(S^1)_{(1, \text{cst})} \xrightarrow{\rho} (S^1 \to U)_{(P)} \xrightarrow{\text{ev}} \text{InfCyc}
\]

Both the left and the right triangle represent identity types. We have an identification for the left triangle because the fiber \(\sum_z:1(x \to z)\) of \(\text{cst}_x\) at \(x:S^1\) can be identified with \(P_z(x) \equiv (z \to x)\), for any \(z:S^1\). For the right triangle we apply circle induction to construct an element of \(\prod_z:S^1 \rightarrow \text{ev}_U(P_z)\). The base case \(z \equiv \_\) is exactly the abovementioned application of Corollary 3.4.6. For the loop case we observe that the following diagram commutes:

\[
\begin{array}{ccc}
Z & \xrightarrow{\mathcal{O}^-} & (\_ \rightarrow \_)
\\ & \downarrow{\mathcal{O}^-} & \downarrow{\mathcal{O}^-}\n\\ Z & \xrightarrow{\mathcal{O}^-} & (\_ \rightarrow \_).
\end{array}
\]

Note that to transport in the family \(\mathcal{P}_z(\_ \rightarrow \_)\), we use Exercise 2.14.4(3), and that is why we picked the predecessor equivalence in Definition 3.5.3. This is also illustrated in Fig. 3.5.\(^{19}\)

With (3.5.1) in hand, we see that \(c\) is an equivalence if and only if either of the two other downward maps are.\(^{20}\)

We now show that the map \((1, \text{cst})\) on the left is an equivalence. Since the codomain is connected, it suffices to show that the fiber at \((1, \text{cst})\) is contractible. This fiber is the sum type \(\sum_z:S^1 ((1, \text{cst}) \rightarrow (1, \text{cst}_z))\), where the identity type is by Lemma 2.10.3 equivalent to pairs of an equivalence \(e:1 \to \mathbb{I}\) and elements of the identity type represented by the triangle

\[
\begin{array}{ccc}
1 & \xrightarrow{e} & S^1
\\ & \searrow{\text{cst}} & \swarrow{\text{cst}_z}
\\ \mathbb{I} & \xrightarrow{\text{cst}} & 1
\end{array}
\]

Since \(1\) is contractible, this just amounts to the identity type \(\_ \rightarrow z\), and \(\sum_z:S^1 (\_ \rightarrow z)\) is indeed contractible.

**Exercise 3.5.4.** Let \(X\) be a type and \(F:X \to U\) a function. Give an equivalence \(e_x\) from the identity type \((y \mapsto (x \to y)) \rightarrow F\) to the type \(F(x)\), for any \(x:X\). Then show that the map sending \(x:X\) to \((y \mapsto (x \to y))\) is an injection.

We now give the second, more direct, proof that \(c\) is an equivalence. For this we use the following lemma, which is of independent interest.

**Lemma 3.5.5.** Let \(X\) and \(Y\) be connected types, \(x\) an element of \(X\), and \(f\) a function from \(X\) to \(Y\). Then \(f\) is an equivalence if and only if \(\text{ap}_f:(x \to x) \rightarrow (f(x) \to f(x))\) is an equivalence.

**Proof.** Using Corollary 2.17.9(2) it suffices to show that each map induced by \(f\) on identity types is an equivalence if and only if the specific map \(\text{ap}_f:(x = x) \rightarrow (f(x) = f(x))\) is an equivalence. Being an equivalence is a proposition, so the result follows in two easy steps from \(X\) being connected, using Exercise 2.16.9. \(\Box\)
Theorem 3.5.6. The function \( c : S^1 \to \text{InfCyc} \) from Definition 3.5.3 is an equivalence.

Proof. In view of Lemma 3.5.5 we only need to show that \( \text{ap}_c \equiv (\bullet \mapsto \bullet) \to ((Z, s) \mapsto (Z, s)) \) is an equivalence. Note that both the domain and the co-domain of \( \text{ap}_c \) have been identified with \( Z \). Consider the following diagram in which we compose \( c \) with the equivalences from Corollary 3.4.6 and Lemma 3.5.2:

\[
\begin{array}{ccc}
Z & \xrightarrow{\omega} & (\bullet \mapsto \bullet) \\
\xrightarrow{\text{ap}_c} & & \xrightarrow{((Z, s) \mapsto (Z, s))} \\
\xrightarrow{\text{ev}_0} & & Z
\end{array}
\]

For \( c \) to be an equivalence, it suffices to show that the composition is an equivalence from \( Z \) to itself. By definition, \( \text{ap}_c(\omega) \) is the identification corresponding to \( s^{-1} \), sending \( 0 \) to \(-1\), and by induction on \( n : Z \) it follows that \( \text{ev}_0(\text{ap}_c(\omega^n)) = s^{-n}(0) = -n \). And the map \( n \mapsto -n \) is indeed an equivalence. \( \square \)

### 3.6 Connected set bundles over the circle

Let \( A \) be a type and \( f : A \to S^1 \) a function. By Corollary 2.17.9(1), \( f \) is a set bundle over \( S^1 \) if and only if each map induced by \( f \) on identity types is injective. Assume that \( f : A \to S^1 \) is a set bundle with \( A \) connected. Let \( a_0 \) be an element of \( A \). By Exercise 2.16.9 the condition that each \( \text{ap}_f \) is injective can be relaxed to \( \text{ap}_f : (a_0 \mapsto a_0) \to (f(a_0) \mapsto f(a_0)) \) being injective. Now look at the following diagram, with \( \text{wdg} \) the winding number function from Exercise 3.4.10 and \( \omega \) from Corollary 3.4.6:

\[
(3.6.1) \quad (a_0 \equiv_{A} a_0) \xrightarrow{\text{ap}_f} (f(a_0) \equiv_{\text{cyc}} f(a_0)) \xrightarrow{\text{wdg}_{f(a_0)}} Z \xrightarrow{\omega} (\bullet \equiv \bullet)
\]

Define the composite \( g_f \equiv \text{wdg}_{f(a_0)} \circ \text{ap}_f \), and consider its image, which is a subset of the integers. Clearly, \( g_f \) is an injection, so that its fibers are propositions, and the image is the subset \( \sum_{n : Z} \text{sym}(n) \). Obviously, a classification of connected set bundles over the circle also classifies certain subsets of \( Z \), or, equivalently, certain subsets of symmetries of \( \bullet \). Such subsets of \( Z \) are closed under addition and negation, and those of \( (\bullet \mapsto \bullet) \) are closed under concatenation and inverses, since \( \text{ap}_f, \text{wdg} \) and \( \omega \) are compatible with these operations. Using language to be introduced in Chapter 5, we actually “classify the subgroups of the integers”.

Recall that set bundles over the circle are equivalent to sets with permutations. Which sets with permutations \( (X, t) \) correspond to connected set bundles? It is not so surprising that the answer has to do with whether any two points \( x, x' : X \) can be connected by applying \( t \) some number of times.

Definition 3.6.1. Let \( X \) be a set with a permutation \( t \). Elements \( x, x' : X \) such that \( x' = t^n(x) \) for some \( n : Z \) are said to be connected by \( t \), denoted \( x \sim x' \) whenever \( t \) is clear from the context. The relation \( \sim \) is an equivalence relation. (Exercise: Check this.) \( \square \)

Recall Fig. 3.2. We now have all the tools to analyze the difference between the left and the right picture in full generality.
Construction 3.6.2. Let \( X \) be a set with a permutation \( t \), defining the equivalence relation \( \sim \) as in Definition 3.6.1. The set bundle over the circle corresponding to \((X,t)\) in Theorem 3.3.8 is the pair \((\sum_{x} E(z), \text{fst})\) where \( E \equiv \text{vec}_{t}(X,t) : S^1 \to \mathcal{U} \), with \( \mathcal{U} \) defined by circle induction in Theorem 3.1.2. Then we have a bijection between \( ||\sum_{x} E(z)||_{0} \) and the quotient \( X/\sim \) as defined in Definition 2.22.10.

Implementation of Construction 3.6.2. Abbreviate \( \sum_{x} E(z) \) by \( A \). We define a map \( g : ||A||_{0} \to X/\sim \), from the set of components of \( A \) to the quotient set of \( X \) using the universal property of set truncation (Definition 2.22.4), pair induction, and circle induction. To define \( g_{0} : \prod_{x} E(z) \to X/\sim \), we put \( g_{0}(\ast) \equiv [\cdot] : X \to X/\sim \) and need \( g_{0}(\circ) : g_{0}(\ast) \to g_{0}(\ast) \), equivalent to \( g_{0}(\ast) \equiv [\cdot] : X \to X/\sim \). The latter we get by function extensionality and Theorem 2.22.12, since \( x \sim t(x) \) for any \( x : X \).

The inverse of \( h : (X/\sim) \to ||A||_{0} \) of \( g \) is defined as the extension of \( h_{0} : X \to ||A||_{0} \) with \( h_{0}(x) \equiv [(\ast), x]_{0} \). We just need to check that \( h_{0}(x) = h_{0}(x') \), or equivalently, \( [(\ast), x] \equiv [\ast]_{A}(\ast, x') \), whenever \( x \sim x' \). Since this is a proposition, if \( x' = t^{n}(x) \) with \( n : Z \), we may use induction on \( n \) (positive and negative) together with the paths, \( (\cup, \text{rel}_{l(z)}) : (\ast, x) \equiv [\ast]_{A}(\ast, t(x)) \), to conclude.

It’s easy to check that \( g \) and \( h \) are mutually inverse. \( \square \)

In Fig. 3.6 we see the set bundle corresponding to the set \( \{1, 2, 3, 4, 5\} \) with the permutation \( 1 \mapsto 2 \mapsto 3 \mapsto 1, 4 \mapsto 5 \mapsto 4 \). There are two components, showing that the permutation splits into two cycles.

Definition 3.6.3. Let \( \text{Cyc} \) be the subtype of \( \sum_{x} \mathcal{T}(X \to X) \) of those pairs \((X, t)\) where \( X \) is a nonempty set with an equivalence \( t \) and any \( x, x' : X \) are connected by \( t \). Expressed in a formula:

\[
\text{Cyc} \equiv \sum_{X : \text{Set}} (||X|| \times \sum_{t : X \sim x \times x'} \exists (x' = t^{n}(x))).
\]

Elements of \( \text{Cyc} \) are called cycles. \( ^{22} \)

Corollary 3.6.4. Under the equivalence described in Construction 3.6.2, connected set bundles over the circle correspond to cycles.

Proof. We use the notations of the implementation of Construction 3.6.2. If \( A \) is connected, then \( ||A||_{0} \) is contractible and hence also \( X/\sim \) is contractible, so \((X, t)\) is a cycle.

Conversely, if \((X, t)\) is a cycle, then \( X/\sim \) is contractible and hence also \( ||A||_{0} \) is contractible, so \( A \) is connected. \( \square \)

We already know some connected set bundles over the circle, namely the universal set bundle, which is also represented by the constant map \( \text{cst} : 1 \to S^1 \), and which we showed is equal to the exponential set bundle, which in turn corresponds to the infinite cycle \((Z, s)\) consisting of the set of integers \( Z \) with the successor permutation. Another example is the left one of the two examples given in Fig. 3.2.

We now introduce the remaining set bundles over the circle, first as functions to the circle, then as families of sets. Eventually we’ll show – assuming a weak form of the Law of the Excluded Middle – that
these (with the universal set bundle) are all the decidable connected set bundles over the circle.

**Definition 3.6.5.** For \( m : \mathbb{N} \) positive, define the degree \( m \) function by circle induction

\[
\delta_m : S^1 \to S^1, \quad \text{setting } \delta_m(\cdot) \equiv \cdot \text{ and } \delta_m(\cup) \equiv \cup^m.
\]

On loops, the degree \( m \) function is the map \((\_)^m : (\cdot \mapsto \cdot) \to (\cdot \mapsto \cdot)\), which is indeed an injection for positive \( m \), so \( \delta_m \) is a set bundle corresponding to the subset of \((\cdot \mapsto \cdot)\) consisting of \( \cup^m : \cdot \mapsto \cdot \) for all \( n : \mathbb{Z} \).

In Section 3.4 we gained a lot of insight into the universal set bundle, \( \text{cst} : 1 \to S^1 \), by constructing an equivalence with the exponential set bundle, see Theorem 3.4.5. In this section, we’ll learn more about the degree \( m \) map, \( \delta_m : S^1 \to S^1 \), by constructing an equivalence with another concrete family.

Fix a positive number \( m : \mathbb{N} \). Recall the finite set \( m \) from Definition 2.24.1 with elements denoted \( 0, 1, \ldots, m-1 \), as well as the equivalence of type \( m \mapsto \sum_{k : \mathbb{N}} k < m \) from Exercise 2.24.2. Hence we may define a successor map \( s : m \to m \) by

\[
s(k) \equiv \begin{cases} 
  k+1 & \text{if } k < m - 1, \\
  0 & \text{if } k = m - 1.
\end{cases}
\]

**Exercise 3.6.6.** Show that \( s : m \to m \) is an equivalence by defining an explicit inverse.

Thus, \((m, s)\) is another key example of a cycle called the standard finite \( m \)-element cycle. As seen in Theorem 3.3.8, any cycle corresponds to a set bundle over \( S^1 \). Just as the set bundle \( R \) in Definition 3.3.12 corresponds to the standard infinite cycle \((\mathbb{Z}, s)\), we will now define the set bundle \( R_m \) corresponding to standard finite \( m \)-element cycle.

**Definition 3.6.7.** Fix \( m : \mathbb{N} \) positive. Define the set bundle \( R_m : S^1 \to \text{Set} \) by \( R_m(\cdot) \equiv m \) and \( R_m(\cup) \equiv \emptyset \). Recall \( \text{Tot}(R_m) \equiv \sum_{z : S^1} R_m(z) \) and point \( \text{Tot}(R_m) \) at \((\cdot, 0)\). Now define

\[
pow_m \equiv \text{fst} : \text{Tot}(R_m) \to S^1 \text{ with pointing path refl.}
\]

We call \( pow_m \) the \( m \)-th power bundle of the circle.

**Remark 3.6.8.** The analogue of our degree \( m \) function is the \( m \)-th power of complex numbers restricted to the unit circle, mapping \( z \) to \( z^m \) if \( |z| = 1 \). If we parameterize the unit circle by the angle \( \theta : \mathbb{R} \) (defined up to multiples of \( 2\pi \)), so \( z = e^{i\theta} \), then \( z^m = e^{im\theta} \). Figure 3.7 illustrates the \( m \)-th power bundle over the circle. Choosing any point \( z \) on the unit circle, we see that the preimage of \( z \) under the \( m \)-th power map is a shifted copy of the \( m \) different \( m \)-th roots of unity inside the unit circle.

To identify \( \delta_m \) and \( pow_m \) as set bundles over \( S^1 \), it suffices to define an equivalence \( \psi_m : \text{Tot}(R_m) \to S^1 \) and an identification \( \alpha_m \) of the identity.
type $\delta_m \psi_m \sim \text{pow}_m$ represented by the triangle below.

$$\begin{array}{c}
\text{Tot}(R_m) \\
\downarrow \psi_m \\
S^1 \\
\downarrow \text{pow}_m \\
S^1 \\
\downarrow \delta_m \\
\end{array}$$

To see how to define $\psi_m$ and $\alpha_m$, we draw in Fig. 3.8 the type $\text{Tot}(R_m)$ unrolled into a “clock”, with marks 0, 1, ..., $m - 1$ (the mark $k$ is the element $(\cdot, k) : \text{Tot}(R_m)$), and arcs following the successor permutation of $m$. We denote these arcs by $a_k \equiv (\bigcirc, \text{refl}_{\text{top}_{k}}) : (\cdot, k) \to (\cdot, s(k))$. The $m$th power map (which is just the first projection) sends each mark to $\cdot : S^1$ and each arc to $\bigcirc$.

This is indicated in blue on the inside of the clock. To define $\psi_m$, we must send all the marks to $\cdot : S^1$ and all arcs to refl., except one, which goes to $\bigcirc$. This is indicated in red on the outside of the clock.

**Construction 3.6.9.** For each positive integer $m$, there is an equivalence $\psi_m : \text{Tot}(R_m) \to S^1$ and an element $\alpha_m : \delta_m \psi_m \sim \text{pow}_m$.

**Implementation of Construction 3.6.9.** Since $\text{Tot}(R_m) \equiv \coprod_{z : S^1} R_m(z)$, to define $\psi_m$ we first split the argument into a pair $(z, k)$. In order to facilitate circle induction we consider $\psi_m$ as an element of the type $\Pi_{z : S^1}(R_m(z) \to S^1)$. We define $\psi_m(z) : R_m(z) \to S^1$ by circle induction on $z$. The base case is $\psi_m(\cdot) \equiv \text{cst.} : m \to S^1$, the constant function at $\cdot$ (recall $R_m(\cdot) \equiv m$). Since transport in a function type is by conjugation (Construction 2.14.2), and the codomain type is constant, we need to give an identification $\psi_m(\bigcirc)$ of type $\psi_m(\cdot) \sim_{\text{pow}_{m-1} - \text{pow}_{m-1}} \psi_m(\cdot) R_m(\bigcirc)$. We construct $\psi_m(\bigcirc)$ using function extensionality, by giving an element in $m \to (\cdot \circ \cdot)$. Since $\psi_m$ needs to send all arcs, except the last, in $\text{Tot}(R_m)$ to reflexivity, we map $k$ to refl. for $k < m - 1$, and we map $m - 1$ to $\bigcirc$.

The inverse of $\psi_m$ maps $\cdot$ to $(\cdot, 0)$, i.e., the mark at 0, and $\bigcirc$ to $a_{m-1} \cdots a_0$, i.e., the product of all the arcs around the circle. We leave it as an exercise to prove that this really defines an inverse to $\psi_m$.

We likewise use function extensionality and pair and circle induction to define $\alpha$, reducing the problem to giving (with a slight abuse of notation) $\alpha_m(\cdot, k) : \text{pow}_m(\cdot, k) \sim \delta_m(\psi_m(\cdot, k))$ together with elements $\alpha_m(\bigcirc, k)$ witnessing that the two composites agree in the square

$$\begin{array}{c}
\text{pow}_m(\cdot, k) \\
\downarrow \alpha_m(\cdot, k) \\
\delta_m(\psi_m(\cdot, k)) \\
\downarrow \delta_m(\psi_m(\cdot, k)) \\
\text{pow}_m(\cdot, s(k)) \\
\downarrow \alpha_m(\cdot, s(k)) \\
\delta_m(\psi_m(\cdot, s(k))) \\
\end{array}$$

In Fig. 3.9 we show these $m$ squares with the left and right hand sides simplified according to the definitions.

We see that we can pick $\alpha_m(\cdot, k) \equiv \bigcirc^{m-k}$, and then we can take for $\alpha_m(\bigcirc, k)$ the trivial proofs that refl. $\bigcirc^{m-k} = \bigcirc^{-(k+1)} \bigcirc$, for $k < m - 1$, and $\bigcirc^{m} \sim \bigcirc^{-(m-1)} \bigcirc$, for $k = m - 1$. □

In Fig. 3.10, which is an adaptation of Fig. 3.8, we illustrate the last part of the above construction in the case $m = 5$.

The labels on the inner arcs show pow$_3(\bigcirc, k)$, on the outer arcs $\delta_5 \psi_5(\bigcirc, k)$, and on the radiuses $\alpha_m(\cdot, k)$. The proofs $\alpha_m(\bigcirc, k)$ prove the commutativity of the five squares in circular arrangement.
Corollary 3.6.10. The degree $m$ map $\delta_m : S^1 \to S^1$ is a connected set bundle for each positive integer $m$, and all the preimages $\delta_m^{-1}(z)$, $z : S^1$, are $m$-element finite sets.

We get an explicit equivalence $m \cong \delta_m^{-1}(\cdot)$ from $\psi_m$ and $\alpha_m$: send $k$ to $(\cdot, \mathcal{O}^{-1})$, using the following exercise.

Exercise 3.6.11. Let $A, B, C$ be types and $f : A \to C$, $g : B \to C$ functions. Assume moreover we have an equivalence $e : A \to B$, an element $h : \prod_{x : A} f(x) \cong g(e(x))$, and an element $c : C$. Show that $(a, p) \mapsto (e(a), h(a)p)$ defines an equivalence $f^{-1}(c) \cong g^{-1}(c)$.

Recall that our goal is to understand the type of set bundles over the circle. Since the type of set bundles is equivalent to $S^1 \to \text{Set}$, and $\text{Set}$ is a groupoid (Lemma 2.22.1), Lemma 2.15.5(1) gives that the type of set bundles over the circle is a groupoid. We will pin this groupoid down by first analyzing the sets of identifications in it.

To do this, we generalize Lemma 3.5.2 to other kinds of cycles. However, since we’re dealing with multiple components, it’ll be useful to have a set labeling the components first.

Definition 3.6.12. For any cycle $(X, t)$, let $H_t \equiv \{ n : Z | t^n = \text{id} \} : \text{Sub}_Z$. Thus, $H_t$ is the subset of $Z$ determined by the predicate $t^n = \text{id}$ for $n : Z$. Recall Corollary 2.25.7 implying that $\text{Sub}_Z$ is a set.

Lemma 3.6.13. Let $(A, f)$ be a connected set bundle over the circle with corresponding cycle $(X, t)$ according to Corollary 3.6.4. For any $x : X$ we have $H_t = \{ n : Z | t^n(x) = x \}$, and for any $a : A$, we have that $H_t$ also equals the image of the composite

\[(a \overset{\psi_f}{\to} f(a)) \overset{\psi_{t^n}}{\to} Z,\]

where the second map is the winding number function from Exercise 3.4.10.

Proof. We may suppose that the set bundle $(A, f)$ over the circle has the form $(\sum_{z : S^1} E(z), \text{fst})$, where $E \equiv \text{vec}(X, i) : S^1 \to \mathcal{U}$ is the family corresponding to the cycle $(X, t)$. To prove the proposition in the lemma quantifying over $A$, i.e., over $z : S^1$ and $x : E(z)$, it suffices to consider the case $z \equiv \cdot$ and $x : X$, since the circle is connected.

For any point $x : X$, corresponding to the point $a \equiv (\cdot, x) : A$, the type $(a \overset{\psi_f}{\to} f(a))$ is equivalent to $\sum_{n : Z} t^n(x) = x$ in such a way that the composite function $(3.6.2)$ corresponds to the first projection. Hence the image of $(3.6.2)$ is precisely $\{ n : Z | t^n(x) = x \}$.

It remains to show that $\{ n : Z | t^n(x) = x \} \subseteq H_t$ (the other inclusion being clear). So assume $t^n(x) = x$. Then if $x' : X$ is any other point, to prove the proposition $t^n(x') = x'$, we may assume we have $k : Z$ with $x' = \bar{t}^k(x)$. Then $t^n(x') = \bar{t}^{n+k}(x) = \bar{t}^k(x) = x'$, as desired.

Lemma 3.6.14. Let $(X, t)$ and $(Y, u)$ be cycles. The following propositions are equivalent:

1. $\|(X, t) \overset{\psi}{\to} (Y, u)\|$
2. $H_t = \text{Sub}_{(Y, u)} H_u$
3. For all $x_0 : X$, $y_0 : Y$, the type $\sum_{z : (X, t)} \text{eq}(Y, u) e(x_0) = y_0$ is contractible.
Proof. Proving (2) from (1) is easy, since (2) is a proposition.

Assume (2), i.e., for any \( x : X, \ y : Y \) and \( n : \mathbb{Z}, t^n(x) = x \) if and only if \( u^n(y) = y \). In order to prove (3), let \( x_0 : X \) and \( y_0 : Y \). We must determine a unique equivalence \( e : X \rightarrow Y \) such that \( et = ue \) and \( e(x_0) = y_0 \).

A necessary condition that \( e \) has to fulfill is the following. For any \( x : X \) and \( n : \mathbb{Z} \) with \( x = t^n(x_0) \), we must have

\[
e(x) = e(t^n(x_0)) = u^n(e(x_0)) = u^n(y_0).
\]

This shows uniqueness of \( e \) once its existence has been established. For showing existence, we use that for any \( x : X \) there exists an \( n : \mathbb{Z} \) with \( x = t^n(x_0) \) and that \( u^n(y_0) \) is independent of such \( n \). Technically, to use the proposition \( \exists n : \mathbb{Z}(x = t^n(x_0)) \) to construct \( e(x) : \mathbb{Y} \), we prove instead that the type \( P_x : \equiv \sum_{y : \mathbb{Y}} \prod_{n : \mathbb{Z}} ((x = t^n(x_0)) \rightarrow (y = u^n(y_0))) \) is contractible, and define \( e(x) \) to be its center. Note that \( P_x \) is a subtype of \( \mathbb{Y} \) (the product part is a proposition since \( \mathbb{Y} \) is a set).

Let \( x : X \). Since being contractible is a proposition we may assume a \( m : \mathbb{Z} \) with \( x = t^m(x_0) \). As center of \( P_x \) we take \( y = u^m(y_0) \). We need to show, for any \( n : \mathbb{Z} \), that \( x = t^m(x_0) = t^n(x_0) \) implies \( u^m(y_0) = u^n(y_0) \). But this follows from our starting assumption, since the former is equivalent to \( t^{m-n}(x_0) = x_0 \) and the latter to \( u^{m-n}(y_0) = y_0 \). Note that we also get \( e(x_0) = y_0 \) as the center of \( P_{x_0} \). We still need to show that any two \( y, y' \) in \( P_x \) are equal. But this is clear, since \( x = t^m(x_0) \), so \( y = u^m(y_0) = y' \).

It's easy to prove the proposition that this \( e \) is indeed an equivalence, so this is left to the reader.

Finally, we prove that (1) follows from (3). This is almost immediate: since (1) is a proposition we may assume \( x_0 : X \) and \( y_0 : Y \) and use the center of contraction.

The following corollary of Lemma 3.6.14 (3) generalizes Lemma 3.5.2.

**Corollary 3.6.15.** Let \( (X, t), (Y, u) : \text{Cyc} \) and let \( x_0 : X \). If any of (1)–(3) in Lemma 3.6.14 is true, then the function

\[
ev_0 : ((X, t) \xrightarrow{!} (Y, u)) \rightarrow Y \text{ defined by } ev_0(e, !) \equiv e(x_0)
\]

is an equivalence.

As a second consequence, we get the following for the type of loops at the standard \( m \)-cycle.

**Corollary 3.6.16.** For cycles \((m, s)\), evaluation at \( 0 : m \) gives an equivalence \((m, s) \xrightarrow{!} (m, s) \xrightarrow{ev_0} m \) with \( ev_0(\text{refl}_{(m, s)}) = 0 \), and composition with the identification \((s, !) : (m, s) \xrightarrow{!} (m, s) \) corresponds to the operation \( s : m \rightarrow m \), that is, the diagram in the margin commutes.

**Remark 3.6.17.** In Corollary 3.6.16, the equivalence \( s : m \rightarrow m \) is not uniquely determined by the stated property. Its inverse would give the same result for any \( m \) (even for \( \mathbb{Z} \)). In fact there are as many as there are positive integers less than \( m \) that are relatively prime to \( m \). This behavior has number theoretic consequences and origins and will be investigated further when we have the proper machinery to put it to good use.

And as a third consequence, we get a more concrete description of the set of components of \( \text{Cyc} \), and hence, by Corollary 3.6.4, of the type of connected set bundles over the circle.
Corollary 3.6.18. Let $H : \text{Cyc} \to \text{Sub}_Z$ be the map sending $(X, t)$ to $H_t$. Then the image of $H_t$ is equal to the the subset of $\text{Sub}_Z$ consisting of those $H \subseteq Z$ that contain 0 and are closed under addition and negation.

Proof. Recall $\text{im}(H_t) \equiv \sum H : \text{Sub}_Z \exists (X, t) : \text{Cyc}(H = H_t)$. Let $H : \text{Sub}_Z$. We have to prove that $\exists (X, t) : \text{Cyc}(H = H_t)$ if and only if $H \subseteq Z$ contains 0 and is closed under addition and negation. Assume $\exists (X, t) : \text{Cyc}(H = H_t)$. Since we have to prove a proposition, we may assume we have a cycle $(X, t)$ with $H = H_t$. Now the required properties of $H$ follow immediately from the definition of $H_t \equiv \{ n : Z \mid t^n = \text{id} \}$. Conversely, suppose $H \subseteq Z$ contains 0 and is closed under addition and negation. Define the relation $\sim_H$ on $Z$ by setting $z \sim_H z'$ if and only if the difference $z - z'$ is in $H$. This is an equivalence relation: it is reflexive since $H$ contains 0, transitive since $H$ is closed under addition, and symmetric since $H$ is closed under negation. So let $X \equiv Z/\sim_H$, and define $t([z]) \equiv [s(z)]$ for $z : Z$. This is well defined, since $z \sim_H z'$ holds if and only if $s(z) \sim_H s(z')$. It is clear that $(X, t)$ is a cycle with $H_t = H$.

□

Exercise 3.6.19. Let $(X, t)$ and $(Y, u)$ be cycles, and $f : X \to Y$ a map such that $uf = ft$. Show: (i) $H_t \subseteq H_u$; (ii) $f$ is surjective; (iii) if $H_u \subseteq H_t$ then $f$ is also injective.

The components of $\text{Cyc}$ will pop up many times from now on, so we make the following definitions to make it easier to talk about them.

Definition 3.6.20. The type of orders is defined to be $\text{Order} \equiv \| \text{Cyc} \|_0$. We say that the infinite cycle $(Z, s)$ has infinite order, and the standard $m$-cycle $(m, s)$ has finite order $m$, for positive $m : \mathbb{N}$.

We write $\text{ord} \equiv \| \_ : \text{Cyc} \to \text{Order}$ for the map from cycles to their orders, and we write $\text{ord}(t) : \equiv \text{ord}(X, t)$ for short.

We say that the order $d : \equiv \text{ord}(X, t)$ divides the order $k : \equiv \text{ord}(Y, u)$, written $d | k$, for cycles $(X, t), (Y, u)$, if $H_u \subseteq H_t$.

We have a canonical injection $\mathbb{N} \hookrightarrow \text{Order}$, mapping 0 to the infinite order and each positive $n$ to the finite order $n$. The orders in the image are called principal, and we don’t make any notational distinction between a natural number $d$ and the corresponding principal order. As a subset of $Z$ according to Corollary 3.6.18, a principal order is simply $dZ$, so we see that the divisibility relation on orders extends that on natural numbers.

The description in Corollary 3.6.18 is still not as concrete as we’d like. Is it true that any order is principal, in other words, that every cycle has either infinite order or finite order $m$ for some positive $m : \mathbb{N}$? Most other textbooks will tell you that the answer is yes, but the proof is unfortunately not constructive. It makes sense first to restrict to decidable set bundles/cycles. Even so, we need one further non-constructive assumption, namely:

Principle 3.6.21 (Limited Principle of Omniscience). For any given function $P : \mathbb{N} \to 2$, either there is a smallest number $n_0 : \mathbb{N}$ such that $P(n_0) = 1$, or $P$ is a constant function with value 0.

The Limited Principle of Omniscience is weaker than the Law of the Excluded Middle Principle 2.18.2, as we prove in the following lemma.

By $H \subseteq Z$ being closed under addition and negation, we simply mean that if $z, z'$ are in $H$, then so are $z + z'$ and $-z$.

Note that we’re still being cavalier with universe levels. Really, we should write $\text{SetBundle}(\mathbb{S}_Z, \text{Cyc}_Z, \text{Sub}_Z, \text{Order}_Z, \ldots)$ to indicate from which universe $\mathcal{U}$ we draw the types involved. We trust that the reader can fill these in if desired.

This rules out certain pathological cycles, such as the subset $\{ \mathbb{Q} \subseteq \mathbb{R} \subsetneq C \subsetneq Z \}$, with a suitable equivalence, e.g., incrementing the exponent. Here $\mathcal{A} : \mathbb{R}$ is an unknown real number, of which we don’t know whether it is rational or not.

It is also the case that the Limited Principle of Omniscience does not imply the Law of Excluded Middle, because a model that satisfies the Limited Principle of Omniscience but not the Law of Excluded Middle can be built using sheaves over the real line $\mathcal{R}$.

Nevertheless, the Limited Principle of Omniscience is not constructive, for otherwise we could simply decide the truth of every open problem in mathematics that can (equivalently) be expressed by a function $P : \mathbb{N} \to 2$ being constant with value 0. This type of argument was first given by Brouwer.

Here we give an example based on the famous Goldbach conjecture, which states that every even integer greater than 2 is the sum of two primes. Using that the latter two primes are necessarily smaller than the even integer itself, it is possible to (equivalently) express the truth of the Goldbach conjecture by a function $P : \mathbb{N} \to 2$ being constantly 0. Now assume we have a proof $t$ of the Limited Principle of Omniscience in type theory, not using any axioms. Then $t(P)$ is an element of the sum type $\mathcal{P} : \mathcal{L} \mathcal{I} \mathcal{R}$, where $\mathcal{R}$ expresses that the function $P$ is constantly 0, and $\mathcal{L}$ implies the negation of $\mathcal{R}$. By the computational properties of type theory one can compute the canonical form of $(t(P))$, which is either $\text{inl}_r$ for some element $r : \mathcal{R}$, or $\text{inr}_l$ for some element $l : \mathcal{L}$. If $(t(P)) \equiv \text{inr}_l$, the Goldbach conjecture is true, and if $(t(P)) \equiv \text{inl}_r$, the Goldbach conjecture is false. Thus the Goldbach conjecture would be solved, and therefore it is unlikely that $t$ exists. In the appendix we give a longer but decisive argument against the constructivity of the Limited Principle of Omniscience.
Proof. Let \( P : \mathbb{N} \to 2 \). By the Law of Excluded Middle, either \( P \) is constant 0, or there exists some \( n : \mathbb{N} \) such that \( P(n) = 1 \). But in that case we may apply Construction 2.23.4 to conclude that there is a smallest \( n_0 : \mathbb{N} \) such that \( P(n_0) = 1 \).

Exercise 3.6.23. Without using LEM or LPO, show that \((Q(P) \to \text{False}) \to \text{False}\) holds for every function \( Q : \mathbb{N} \to 2 \), where \( Q(P) \) is the proposition obtained by applying the Limited Principle of Omniscience to the function \( P \).

As for the Law of Excluded Middle, we are free to assume the Limited Principle of Omniscience or not, and we will be explicit about where we will use it. The Limited Principle of Omniscience makes it possible to prove that the canonical map \( \mathbb{N} \to \text{Order}^{\text{dec}} \) (the codomain being the subtype of Order given by decidable cycles), is an equivalence. We will elaborate this equivalence in the next paragraphs.

We already know from Corollary 3.6.18 that the map is an injection, and a cycle \((X, t)\) has infinite order if and only if \( H_t = \{0\} \) and it has finite order \( m \) if and only if \( H_t = m\mathbb{Z} \), for positive \( m : \mathbb{N} \).

Fix now a decidable cycle \((X, t)\), and consider the corresponding subset \( H \equiv H_t \equiv \{ n : \mathbb{Z} \mid t^n = \text{id} \} \). This is a decidable subset, since \( t^n = \text{id} \) is a proposition, and \( n \) is in \( H \) if and only if \( t^n(x) = x \) for some/all \( x : X \) (recall that \( X \) is non-empty).

Apply the Limited Principle of Omniscience (Principle 3.6.21) to the function \( P : \mathbb{N} \to 2 \) defined by \( P(n) = 1 \) if \( n + 1 \) is in \( H \), and \( P(n) = 0 \) otherwise. If \( P(n) \) is constant 0, then \( H = \{0\} \), so \((X, t)\) has infinite order. (As a set bundle, it is then equivalent to the universal set bundle.)

Otherwise, if \( n_0 \) is the smallest natural number with \( m \equiv n_0 + 1 \) in \( H \), then we claim \( H = m\mathbb{Z} \), from which it follows that \((X, t)\) has order \( m \).

Clearly, \( m\mathbb{Z} \subseteq H \), since if \( t^n = \text{id} \), then also \( t^{kn} = \text{id} \). And if \( t^q = \text{id} \), then by Euclidean division of integers, cf. Lemma 2.23.8, there exist \( k : \mathbb{Z} \) and \( r : \mathbb{N} \) with \( r < m \) so that \( q = km + r \). Now, the number \( r \) is in \( H \), since \( t^{r} = t^{km + r} = \text{id} \), and is less than the minimal positive value \( m \) in \( H \), and so we must conclude that \( r = 0 \). In other words, \( q \) is a multiple \( km \), as desired.

We summarize these results in the following lemma.

Lemma 3.6.24. The Limited Principle of Omniscience (Principle 3.6.21) implies that the type of connected decidable set bundles over the circle is the sum of the component containing the universal set bundle and for each positive integer \( m \), the component containing the \( m \)-fold set bundle.

Remark 3.6.25. The reader may wonder how the “orientation reversing” map \( r : S^1 \to S^1 \) given by \( r(\cdot) \equiv \cdot \) and \( r(\cup) \equiv \cup^{-1} \) fits into the picture.\(^{27}\) As connected decidable set bundles, we have \((S^1, r) \cong (S^1, \text{id})\), since \( r \) is an equivalence:

\[
\begin{array}{ccc}
S^1 & \xrightarrow{r} & S^1 \\
\downarrow \cong & & \downarrow \text{id} \\
S^1 & & \\
\end{array}
\]

This is a special case of the general case of an equivalence \( e : A \to A' \) depicted in the diagram in the margin, implying \((A, f \circ e, !) \cong (A', f, !)\).

The point is that the degree \( m \) and degree \( -m \) maps give the same bundles (by composing with \( r \)), while as maps they are different.\(^{27}\)

\(^{26}\)This is why it’s natural to associate to \( 0 : \mathbb{N} \) the infinite order.

\(^{27}\)As an operation on infinite cycles, see Definition 3.5.3: \( \text{InfCyc} \to \text{InfCyc} \) maps \((X, t)\) to \((X, t^{-1})\), flipping the arrows.
3.7 Interlude: combinatorics of permutations

In this section, we take a break from analyzing set bundles in order to look more closely at permutations themselves, in particular permutations of finite sets. In Fig. 3.11 we depict the same permutation as in Fig. 3.6, but “unfolded”.

It will be useful to have a more concise notation for permutations. The permutation \( \sigma \) will be denoted \( (1 \ 2 \ 3)(4 \ 5) \). The two groups of parentheses indicate the two cycles, and the order within a group indicates the cyclic order. Since the starting point in a cycle doesn’t matter, we could also have written, e.g., \( (3 \ 1 \ 2)(5 \ 4) \).

In general, if \( a_1, a_2, \ldots, a_k \) are pairwise distinct elements of a decidable set \( A \), then we write \( (a_1 \ a_2 \ \cdots \ a_k) \) for the permutation of \( A \) that maps \( a_1 \) to \( a_2 \), \( a_2 \) to \( a_3 \), \ldots, \( a_k \) to \( a_1 \), and leaves any other elements untouched. Such a permutation is called a cyclic permutation or, somewhat confusingly, a cycle. If we want to specify the length, we call it a \( k \)-cycle. A 2-cycle is also called a transposition.

**Remark 3.7.1.** Any cycle \((X, t)\) in the sense of Definition 3.6.3 (i.e., a cyclically ordered set) gives rise to a permutation \( t \) of \( X \) consisting of a single cycle. If \( X \) is an \( n \)-element set and \( x_0: X \), then we can write this permutation in cycle notation as \((x_0 \ t(x_0) \ \cdots \ t^{n-1}(x_0))\).

Any permutation \( t \) on a set \( X \) corresponds via Theorem 3.3.8 to a set bundle over \( S^1 \), \( p: A \to S^1 \). Writing \( A \) as a sum of its connected components, we express this set bundle as a sum of connected set bundles, but these correspond to cycles by Corollary 3.6.4. Note that cyclic permutations can move at most finitely many elements, and cannot give, e.g., the infinite cycle \((Z, s)\). Moreover, to define the cycle \((X, t)\) from, e.g., the transposition \((x \ x')\) requires that the set \( X \) is decidable.

**Definition 3.7.2.** Let \( A \) be a set with a permutation \( \sigma \). If \( \sigma(a) = a \), we say that \( a \) is a fixed point of \( \sigma \). If \( \sigma(a) \neq a \), we say that \( a \) is moved by \( \sigma \). The support of \( \sigma \) is the subset of \( A \) consisting of the elements that are moved by \( \sigma \).

Note that if \( A \) is decidable, then we can decide whether an element is moved or is a fixed point.

**Exercise 3.7.3.** Let \( A \) be a decidable set with two permutations \( \sigma, \tau \). Show that if \( \sigma, \tau \) have disjoint supports, then they commute in the sense that \( \sigma \tau = \tau \sigma \).

**Exercise 3.7.4.** Prove that a \( k \)-cycle permutation of a decidable set \( A \) can be written as a composition of \( k - 1 \) transpositions by verifying the identity

\[
(a_1 \ a_2 \ \cdots \ a_k) = (a_1 \ a_k)(a_1 \ a_{k-1}) \cdots (a_1 \ a_2).
\]

**Corollary 3.7.5.** Any permutation of a finite set can be expressed as a composition of transpositions.

To show this, first write the permutation as a composition of cyclic permutations, then apply Exercise 3.7.4 to each cycle.

**Exercise 3.7.6.** Show that there are \( n! \) permutations of a finite set of cardinality \( n \), where \( n! := \text{fact}(n) \) is the usual notation for the factorial function.

---

28Thus, disjoint cycles commute, so when we express a permutation on a finite set as a product of disjoint cycles, the order doesn’t matter.

29This representation is not unique, as for example \((1 \ 2)\) = \((2 \ 3)(1 \ 3)(2 \ 3)\) as permutations of \(\{1, 2, 3\}\). However, in Corollary 4.5.9 below, we’ll show that the parity (odd/even) of the number of transitions is invariant.
Hint: One way (not the only one) is to construct bijections \( \text{Aut}(0) \cong 1 \) and

\[
\text{Aut}(A \sqcup I) \cong (A \sqcup I) \times \text{Aut}(A)
\]

for all finite sets \( A. \)

Exercise 3.7.7. Let \( A \) be a finite set of cardinality \( n \) and assume \( 0 \leq k \leq n \).
Show that the number of \( k \)-element subsets of \( A \) is given by the binomial coefficient

\[
\binom{n}{k} = \frac{n!}{k!(n-k)!}.
\]

Find a formula for the number of \( k \)-cycle permutations of \( A \) using factorials and/or binomial coefficients.

3.8 The \( m \)th root: set bundles over the components of \( \text{Cyc} \)

Let’s first give names to some important components of \( \text{Cyc} \) that we have met in previous sections, e.g., in Lemma 3.6.24.

Definition 3.8.1. Define \( \text{Cyc}_0 \coloneqq \text{Cyc}((Z,s)) \). For each positive \( m : \mathbb{N} \), define \( \text{Cyc}_m \coloneqq \text{Cyc}((m,s)) \). We call \( \text{Cyc}_0 \) and \( \text{Cyc}_m \) the type of infinite cycles and type of \( m \)-cycles, respectively.

Recall the equivalence \( c : S^1 \cong \text{Cyc}_0 \) of Definition 3.5.3 between the circle and the type of infinite cycles. In this section, we reinterpret the degree \( m \) function \( \delta_m \) as a map of infinite cycles. In fact \( \delta_m \) makes sense as a map on all cycles, and we’ll use it to begin the classification of the connected set bundles over \( \text{Cyc}_n \), for positive integers \( n \). That’s why it’s instructive to rephrase connected set bundles over \( S^1 \) in terms of cycles, even though they could just be transported along the identification \( \tilde{c} : S^1 \cong \text{Cyc}_0 \) corresponding to \( c \).

Before we do the degree \( m \) maps, let’s note that the universal set bundle over \( \text{Cyc}_0 \) is represented by the constant function \( \text{cst}_0 : 1 \to \text{Cyc}_0 \), sending the unique element of \( 1 \) to \( pt_0 \coloneqq (Z,s) : \text{Cyc}_0 \), the standard infinite cycle.

For the rest of this section, we fix some positive \( m : \mathbb{N} \). We now give a description of the \( m \)-fold set bundle over the circle in terms of cycles.

We proceed as follows. First we present the answer, a set bundle we call \( \rho_m : \text{Cyc}_0 \to \text{Cyc}_0 \), and then we prove that \( \delta_m : S^1 \to S^1 \) and \( \rho_m : \text{Cyc}_0 \to \text{Cyc}_0 \) correspond to each other (and to \( \text{pow}_m : \text{Tot}(R_m) \to S^1 \)) under the equivalence \( c : S^1 \cong \text{Cyc}_0 \).

What should we require of \( \rho_m(X,t) \) for \( (X,t) : \text{Cyc}_0 \)? Well, \( \delta_m : S^1 \to S^1 \) sends \( \cdot \) to \( \cdot \) and \( \cup \) to \( \cup^m \); only the \( \cup^k \) where \( k \) is a multiple of \( k \) is in the image of \( \delta_m \). So we have to find an infinite cycle \( (Y,u) \) with “\( u \)“ corresponding to \( t \”. We achieve this by “stretching” \( X \): Let \( Y \) be \( m \) copies of \( X \) and let \( n \) jump idly from one copy to another except every \( m \)th time when \( u \) also is allowed to use \( t \). This is illustrated in Fig. 3.12 with the shift by \( t \) being vertical and the movement from copy to copy going around a circle.

Construction 3.8.2. For any type \( X \) and \( t : X \to X \), we define the \( m \)th root

\[
\sqrt[m]{t} : (m \times X) \to (m \times X).
\]
Implementation of Construction 3.8.2. We set
\[ \sqrt{t}(k, x) := \begin{cases} (k + 1, x) & \text{for } k < m - 1 \text{ and} \\ (0, t(x)) & \text{for } k = m - 1. \end{cases} \]

Only one \( m \th \) of the time does \( \sqrt{t} \) use \( t : X \to X \), the rest of the time it applies the successor in \( m \). Indeed, iterating \( \sqrt{t} \) we get an identification of type \((\sqrt{t})^m(k, x) \simeq (k, t(x))\); hence the term "\( m \th \) root" is apt.

**Definition 3.8.3.** The formal \( m \th \) root function is defined by:
\[ \rho_m : \sum_{X : \mathcal{U}} (X \to X) \to \sum_{X : \mathcal{U}} (X \to X), \quad \rho_m(X, t) \equiv (m \times X, \sqrt{t}). \]

We use \( \rho \) for "root" to denote this incarnation of the degree \( m \) function.

**Lemma 3.8.4.** If \( t : X \to X \) is an equivalence, then so is \( \sqrt{t} : (m \times X) \to (m \times X) \).

**Proof.** Let \( t : X \to X \) be an equivalence. We prove that the fibers of \( \sqrt{t} \) are contractible.

For the fiber at \((0, x)\) we note, using Lemma 2.10.3, that identifications in \((0, x) \simeq (\sqrt{t})(\ell, y)\) consist of pairs of proofs of \( \ell = m - 1 \) and identifications in \( x \simeq t(y) \). Both \( \sum_{\ell : m} \ell = m - 1 \) and \( t^{-1}(x) \) are contractible, and so \( (\sqrt{t})^{-1}(0, x) \) is contractible.

For the fiber at \((k, x)\) with \( k : m \) not \( 0 \), identifications in \((k, x) \simeq (\sqrt{t})(\ell, y)\) consist of pairs of proofs of \( \ell + 1 = k \) and identifications in \( x \simeq y \), so \( (\sqrt{t})^{-1}(k, x) \) is contractible since both \( \sum_{\ell : m} \ell + 1 = k \) and \( \sum_{\ell : m} \ell = m - 1 \).

**Lemma 3.8.5.** Let \( X : \mathcal{U} \) and \( t : X \to X \). If \((X, t)\) is a cycle, then so is \( \rho_m(X, t) \).

**Proof.** Clearly, \( m \times X \) is a nonempty set if \( X \) is. We already know \( \sqrt{t} \) is an equivalence if \( t \) is. For connectedness, let \((k, x), (k', x') : (m \times X)\). We need to show the proposition that there exists \( n : Z \) with \((k', x') = (\sqrt{t})^n(k, x)\). Let \( n : Z \) be such that \( x' = t^n(x) \). Then \((\sqrt{t})^n(k, x) = (k, t^n(x)) = (k, x')\), so if \( k = k' \) we’re done. Assume \( k < k' \). Then \((\sqrt{t})^{k'-k}(k, x') = (k', x')\), so \( (\sqrt{t})^{n+k'-k}(k, x) = (k', x') \), as desired. The case \( k > k' \) is similar.

The question now arises: how does \( \rho_m \) act on the components of \( \text{Cyc} \), and what can we say about the preimages \( \rho_m^{-1}(X, t) \) for an arbitrary cycle \((X, t)\)?

The first part is easy, since the product of \( m \) with an \( n \)-element set is an \( mn \)-element set.

**Lemma 3.8.6.** The degree \( m \) function restricts to give pointed maps
\[ \rho_m : \text{Cyc}_n \to \text{Cyc}_{mn} \quad \text{and} \quad \rho_m : \text{Cyc}_0 \to \text{Cyc}_0. \]

**Proof.** Recall Definition 3.8.1. The components \( \text{Cyc}_k \) are pointed by \( \text{pt}_0 \equiv (Z, s) \) if \( k = 0 \), and \( \text{pt}_k \equiv (k, s) \) else. Note that the function \( \varphi : (m \times Z) \to Z \) given by \( \varphi(k, r) \equiv k + m r \) is an equivalence, with inverse given by Euclidean division by \( m \). Moreover, we have \( \varphi \sqrt{s} = s \varphi \), since
\[ \varphi(\sqrt{s}(k, r)) = k + 1 + m r = s(\varphi(k, r)) \quad \text{for all } (k, r) : m \times Z. \]
This shows that \( \varphi \) gives an identification of infinite cycles \((m \times Z, \sqrt[n]{s}) \xrightarrow{\sim} (Z, s)\), and hence the \( m \)-th root construction maps the component \( \text{Cyc}_0 \) to itself.

Analogously, we can restrict \( \varphi \) to an equivalence \( m \times n \xrightarrow{\sim} \sum_{k < mn} (k < mn) \), and get an identification of cycles \( \rho_m(\text{pt}_n) \xrightarrow{\sim} \text{pt}_{mn} \), showing that \( \rho_m \) maps the component \( \text{Cyc}_n \) to the component \( \text{Cyc}_{mn} \). \( \square \)

We now analyze how \( \rho_m \) acts on paths. Let \((\bar{e}, !): (X, t) \xrightarrow{\sim} (X', t')\). Since \( \rho_m \) maps first components \( X \) to \( m \times X \), we get that the first projection of \( \text{ap}_{\rho_m}(\bar{e}, !) \) is \( (m \times X) \xrightarrow{\sim} (m \times X') \). We are particularly interested in the case of the loops, that is, \((\bar{e}, !): (X, t) \xrightarrow{\sim} (X, t)\). We calculate \( (id \times e)(k, x) = (k, e(x)) \), which by the property of the \( m \)-th root is equal to \((\sqrt[n]{e})^m(k, x)\). In particular, if we take \( e \equiv t^{-1} \), then we get \( (id \times t^{-1}) = (\sqrt[n]{t^{-1}})^m \), which means that \( \text{ap}_{\rho_m}(t^{-1}, !) \) is indeed the \( m \)-th power of a generating loop at the image cycle \( \rho_m(X, t) \). In particular, this holds for the standard infinite cycle \((Z, s): \text{Cyc}_0 \) and the standard \( n \)-cycle \((n, s): \text{Cyc}_n \).

Why does \( \rho_m: \text{Cyc}_0 \rightarrow \text{Cyc}_0 \) correspond to the \( m \)-fold set bundle we defined in Definition 3.6.5? Recall the equivalence \( c: S^1 \rightarrow C \) from Definition 3.6.5. For the two \( m \)-fold covers to correspond under this equivalence we need an element in the identity type represented by

\[
\begin{array}{ccc}
S^1 & \xrightarrow{c} & \text{Cyc}_0 \\
\beta_m & \downarrow & \downarrow \rho_m \\
S^1 & \xrightarrow{c} & \text{Cyc}_0.
\end{array}
\]

That is, we need an element in \( \rho_m c \xrightarrow{\sim} \text{Cyc}_0 \). Under the equivalence \( ev_{\text{Cyc}_0} : (S^1 \rightarrow \text{Cyc}_0) \xrightarrow{\sim} \sum_{(X, t) : \text{Cyc}_0} ((X, t) = (X, t)) \) of Theorem 3.1.2, the composite \( c \beta_m \) is given by \(((Z, s), s^{-m})\) and the composite \( \rho_m c \) is given by \(((m \times Z, \sqrt[n]{s}), id \times s^{-1})\): we must produce an element in \((m \times Z, \sqrt[n]{s}), id \times s^{-1}) \xrightarrow{\sim} ((Z, s), s^{-m})\).

Consider the equivalence \( \varphi: (m \times Z) \xrightarrow{\sim} Z \) with \( \varphi(k, n) \equiv k + mn \) also used in Lemma 3.8.6. discussed above. Transport of \( \sqrt[n]{s} \) along \( \varphi \) is exactly \( s \), i.e., \( \sqrt[n]{s} = s \varphi \). Likewise, transport of \( id \times s^{-1} \) along \( \varphi \) is \( s^{-m} \), so that \( \varphi \) lifts to an element in \((m \times Z, \sqrt[n]{s}), id \times s^{-1}) \xrightarrow{\sim} ((Z, s), s^{-m})\).

**Exercise 3.8.7.** Extend the above construction to an identification of type \( \rho_m c \xrightarrow{\sim} \text{Cyc}_0 \). \( c \beta_m \) in case these maps are taken to be pointed. \( \downarrow \)

So we know that the fiber of \( \rho_m \) at an infinite cycle \((X, t)\) is an \( m \)-element set. In fact, we will identify this set as \( X/m \equiv X/\sim_m \) where \( \sim_m \) is the isomorphism relation that identifies points that are a distance \( mr \) apart, for some \( r: Z \). Formally, let \( x \sim_m x' \) if and only if \( \exists r: Z(x' = t^{mr}(x)) \). (Such an \( r \) is unique if it exists.) Indeed, the fiber is

\[
\sum_{(Y, u): \text{Cyc}_0} ((X, t) \xrightarrow{\sim} (m \times Y, \sqrt[n]{u})).
\]

We sketch an equivalence from \( X/m \) to \( \rho_m^{-1}(X, t) \). See Construction 3.8.11 below for a careful proof of a more general statement for arbitrary cycles, 34Note that we formulate this in such a way that we don’t need to talk about the inverse of \( \varphi \). Of course, the inverse of \( \varphi \) maps \( z: Z \) to the remainder and the integer quotient of \( z \) under Euclidean division by \( m \), cf. Lemma 2.23.8.
not only infinite ones. Let $Y$ be an equivalence class of $X/m$, taken as a set. One should think of $Y$ as a set $\{\ldots, t^{-2m}(x), t^{-m}(x), x, t^m(x), t^{2m}(x), \ldots\}$ for some $x : X$. Then $(Y, t^m)$ is an infinite cycle and we can construct a natural\footnote{The map defined by $e(k, x) \equiv t^k(x)$ is an equivalence from $m \times Y$ to $X$ such that $te = e'\sqrt{m}$.} identification $i : (X, t) \to (m \times Y, \sqrt{m})$, so that $(Y, t^m, i) : \rho^m_m(X, t)$. The map $Y \mapsto (Y, t^m, i)$ is the intended equivalence.

The reader will no doubt have noticed that $X/m$ is a finite cycle. We’ll return to the significance of this below in Section 3.9.

Our next step is to identify the fiber of $\rho_m$ over a general cycle $(X, t)$. Classically, the remaining cases are those of finite $n$-cycles, but it’s illuminating to be a bit more general. Note that the equivalence relation $\sim_m$ defined above for an infinite cycle makes sense for all cycles.

**Lemma 3.8.8.** For any order $d$ : Order, the type $\Sigma(X, t) : \text{Cyc}_d X$ is contractible, where $\text{Cyc}_d$ denotes the component of $\text{Cyc}$ consisting of cycles of order $d$.

**Proof.** First we note that the goal is a proposition. Clearly, for any cycle $(Y, u)$, the singleton type $\Sigma(X, t) : \text{Cyc}_d Y \to (X, t)$ is contractible. Using Lemma 3.6.14 and Corollary 3.6.15, it follows that $\Sigma(X, t) : \text{Cyc}_d X$ is contractible. Now the lemma follows by set truncation elimination. \qed

**Lemma 3.8.9.** For any cycle $(X, t)$, if $(\sqrt{m})^n = \text{id}_{m \times X}$, then $m$ divides $n$, i.e., $n = mq$ for some $q : Z$, and $t^n = \text{id}_X$. In other words, $m$ divides the order of $\sqrt{m}$.

This follows simply by looking at the first component, where $\sqrt{m}$ acts as the successor operation on $m$. See Definition 3.6.20 for the order.

We’re almost ready to identify the fiber of $\rho_m$ at a cycle $(X, t)$. Let’s explore first the problem of finding an identification of $(X, t)$ with $\rho_m(Y, u) \equiv (m \times Y, \sqrt{m})$ for a given cycle $(Y, u)$. By Lemma 3.6.14, a necessary condition for such an identification is $H_t = \text{Sub}_X H_{\sqrt{m}}$. Recall from Definition 3.6.12 that $H_t \equiv \{n : Z | t^n = \text{id}_X\}$ and $H_{\sqrt{m}} \equiv \{n : Z | (\sqrt{m})^n = \text{id}_{m \times X}\}$. We know from Lemma 3.8.9 that $m$ divides the order of $\sqrt{m}$, so the fiber $\rho_m^{-1}(X, t)$ is nonempty only if $m$ divides the order of $t$.

A key ingredient for the converse is the following.

**Lemma 3.8.10.** Let $(X, t) : \text{Cyc}$ be a cycle with order divisible by $m$ and let $x_0$ be an element of $X$. Then the map $f : m \to X/m, f(k) := [t^k(x_0)]$ is an equivalence.

**Proof.** Fix an equivalence class $V : X/m$ and consider its preimage under $f$, $f^{-1}(V) \equiv \Sigma k : m(V = [t^k(x_0)])$. The contractibility of this type is a proposition, so we may choose $x : X$ with $V = [x]$. Then $V = [t^k(x_0)] \equiv ([x] = [t^k(x_0)]) \equiv (x \sim_m t^k(x_0))$. So we need to show that $\Sigma k : m(x \sim_m t^k(x_0))$ is contractible. More simply, we need to show that there is a unique $k$ with $x \sim_m t^k(x_0)$. Since $(X, t)$ is a cycle, we may further choose $n : Z$ with $x = t^n(x_0)$. By Euclidean division, write $n = qm + r$ with $q : Z, r : m$. Then $x = t^n(x_0) \sim_m t^r(x_0)$, so we have our center. Let $k : m$ also satisfy $x \sim_m t^k(x_0)$. We need to show the proposition $k = r$. But $t^{r-k}(x_0) \sim_m x_0$, so we may take $q' : Z$ with $t^{q'm+r-k}(x_0) = x_0$. Since $m$ divides the order of $t$, this implies $r = k$, as desired. \qed

Now we have all the pieces needed to prove the main result.

**Construction 3.8.11.** For any cycle $(X, t)$, we have an equivalence between $\rho_m^{-1}(X, t)$ and $P \times X/m$, where $P$ expresses that $m$ divides the order of $t$, formally $P : (H_t \subseteq mZ)$ (see Definition 3.6.20).\footnote{When $X$ is a decidable set then LPO allows for a simpler formulation: Then $P$ is either false, in which case $\rho_m^{-1}(X, t)$ is empty, or true, in which case the preimage is $X/m$.}
Implementation of Construction 3.8.11. We’ll use Construction 2.9.9, and we first define the function

\[ g : \rho_m^{-1}(X, t) \to P \times X/m, \]

by mapping \((Y, u)\) and an identification of cycles \(e : (X, t) \xrightarrow{\sim} (m \times Y, \sqrt{m})\) to the proof of \(P\) from Lemma 3.8.9 and the class \(V_e \equiv [e^{-1}(0, y)]: X/m,\)

for any \(y : Y.\)\(^{37}\) As a subset of \(X, V_e = \{ x : X | \text{fst}(e(x)) = 0 \}.\)

In the other direction, to define the function

\[ h : P \times X/m \to \rho_m^{-1}(X, t), \]

fix an equivalence class \(V\) of \(X/m,\) and assume that \(m\) divides the order of \(t.\) As in the discussion after Exercise 3.8.7, we take \(V\) as the set of elements in \(X\) that lie in the class \(V.\) Then \((V, t^m)\) is a cycle.\(^{38}\) We also need an identification \((X, t) \xrightarrow{\sim} \rho_m(V, t^m) \equiv (m \times V, \sqrt{m}).\) This we define via a map \(e' : m \times V \to X, e'(k, v) \equiv t^k(v),\) which preserves cycle structure: \(te' = e'\sqrt{m}.\) The map \(e'\) is an equivalence if \(H_i \subseteq H_{\sqrt{m}},\) by Exercise 3.6.19. So let \(n : Z_\sqrt{m}\) and assume that \(t^m = \text{id}_X.\) Then \(P\) implies that we may write \(n = qm\) for some \(q : Z,\) so

\[ (\sqrt{m})^n = (\sqrt{m})^q = (\text{id}_m \times t^m)^q = (\text{id}_m \times t^q) = (\text{id}_m \times \text{id}_V) = \text{id}_{m \times V}.\]

Straight from these definitions, we see that \(g \circ h = \text{id}.\) We leave to the reader to check that \(h \circ g = \text{id}.\)

\(37\) Note that this doesn’t depend on \(y,\) so that Theorem 2.22.8 applies: \((0, y)\) and \((0, y')\) are a distance \(mr\) apart, and \(e^{-1}\) preserves this distance.

\(38\) Indeed \(t^m\) is properly restricted to \(V: \) If \(x\) lies in \(V,\) then so does \(t^m(x).\)

3.9 Higher images

In this section we take a quick break from characterizing the connected set bundles of \(\text{Cyc}_n\) for finite orders \(n\) in order to make good on our earlier promise to say something about the fact that each fiber of \(\rho_m\)
carries a cycle structure. This involves the notion of \(0\)-image of a map, but we might as well introduce the general notion of \(n\)-image while we’re at it.

Recall from Definition 2.17.11 the propositional image \(\sum_{y : B} ||f^{-1}(y)||\) of a map \(f : A \to B.\) The propositional image can be generalized using \(n\)-truncation instead of propositional truncation.

Recall furthermore the image factorization from Exercise 2.17.12:

\[
\begin{array}{ccc}
A & \xrightarrow{f} & B \\
\downarrow{p} & & \downarrow{i} \\
\text{im}(f) & & \\
\end{array}
\]

Here \(p\) is surjective and \(i\) is injective, and any such factorization is equivalent to this one. Both surjectivity (Definition 2.17.1) and injectivity (Definition 2.17.2) rely on the notion of a proposition: all fibers of \(p\) are nonempty and all fibers of \(i\) are propositions.

The uniqueness of the factorization \(f \xrightarrow{\sim} ip\) can be visualized in terms of the two diagonals of the diamond below: for any surjection \(g : A \to X\) and injection \(h : X \to B\) with \(f \xrightarrow{\sim} hg,\) one can construct a (unique) equivalence \(e\) with \(g \xrightarrow{\sim} ep\) and \(i \xrightarrow{\sim} he.\)
The existence of a unique equivalence \( e \) as above is called the *universal property of the propositional image*. Uniqueness of \( e \) above also follows from the following two exercises.

**Exercise 3.9.1.** Let \( A, B, X \) be types and \( i : A \rightarrow B \) an injection. Let \( i_\ast(X \rightarrow A) \rightarrow (X \rightarrow B) \) be postcomposition with \( i \). Show that \( \text{ap}_{i_\ast} : (f \overset{\sim}{\Rightarrow} g) \rightarrow (if \overset{\sim}{\Rightarrow} ig) \) is an equivalence, for any \( f, g : X \rightarrow A \).

**Exercise 3.9.2.** Let \( A, B, Y \) be types and \( p : A \rightarrow B \) be a surjection. Let \( _p : (B \rightarrow Y) \rightarrow (A \rightarrow Y) \) be precomposition with \( p \). Show that \( \text{ap}_{_p} : (f \overset{\sim}{\Rightarrow} g) \rightarrow (fp \overset{\sim}{\Rightarrow} gp) \) is an equivalence, for any \( f, g : B \rightarrow Y \).

We will now define higher images and generalize the notions of injection and surjection such that a similar universal property of higher images can be proved.

**Definition 3.9.3.** Let \( A, B \) be types and let \( f : A \rightarrow B \). We define the \( n \)-image of \( f \) as

\[
\text{im}_n(f) \equiv \sum_{b : B} \|f^{-1}(b)\|_n.
\]

Observe that \( \text{im}_{-1}(f) \equiv \text{im}(f) \).

**Definition 3.9.4.** A type \( A \) is called \( n \)-**connected** if its truncation \( \|A\|_n \) is contractible. A function \( f : A \rightarrow B \) is called \( n \)-**connected** if the fiber \( f^{-1}(b) \) is \( n \)-connected, for each \( b : B \).

Thus, any type is \((-2)\)-connected, since its \((-2)\)-truncation is contractible. Moreover, the \((-1)\)-connected types are precisely the nonempty ones, and the \( 0 \)-connected types are those we have called connected in Definition 2.16.8.

**Definition 3.9.5.** A function \( f : A \rightarrow B \) is called \( n \)-**truncated** if the fiber \( f^{-1}(b) \) is an \( n \)-type, for each \( b : B \).

One may verify now that the \((-1)\)-connected functions are the surjections, and the \((-1)\)-truncated functions are the injections.

There is a factorization \( f \overset{\sim}{\Rightarrow} ip \) of a map \( f : A \rightarrow B \) through its \( n \)-image, where \( p \) is defined by setting \( p(a) \equiv (f(a), (a, \text{refl}_{f(a)}))_n \), and where \( i \) is defined by setting \( i \equiv \text{fst} \), as in the following diagram.

\[
\begin{array}{c}
A \xrightarrow{f} B \\
\downarrow p \quad \downarrow i \\
\text{im}_n(f) \\
\end{array}
\]

The map \( i \) is \( n \)-truncated, because, for any \( b : B \), the fiber \( i^{-1}(b) \) is equivalent to \( \|f^{-1}(b)\|_n \). Furthermore, by Lemma 2.25.2 and the following lemma, \( p \) is \( n \)-connected.

**Lemma 3.9.6.** For every type \( A \), the constructor \( \|\|_n : A \rightarrow \|A\|_n \) is \( n \)-connected.

Recall that \( i_\ast \) and \( _p \) are compact denotations of the maps \( h \mapsto ih \) and \( h \mapsto hp \), respectively.

If \( A \) and \( B \) are sets, then the fibers of \( f : A \rightarrow B \) are sets as well. Hence \( \text{im}_n(f) \) amounts to the set of pairs \((b, a)\) such that \( b = f(a) \), that is, the inverse of the relation that is commonly known as the graph of \( f \).

It is instructive to explore the special case of \( n = -2 \). Every map \( f : A \rightarrow B \) is trivially \((-2)\)-connected. Moreover, \( \text{fst} : \text{im}_{-2}(f) \rightarrow B \) is an equivalence and \((-2)\)-truncated maps are precisely equivalences. Thus the factorization of \( f : A \rightarrow B \) through its \((-2)\)-image can go through \( B \) and be identified with \( f \overset{\sim}{\Rightarrow} \text{id}_B f \).
Proof. We have to prove that the \(n\)-truncation of each fiber of \(\lfloor \| \rfloor_n\) is contractible. We start by defining a function \(c : \prod_{x : A \equiv B} \| x \|_n \to \lfloor a \|_n \|_n\), producing the centers. Since \(c\) takes values in \(n\)-types, we can define \(c\) by \(n\)-truncation elimination by setting \(c(a) = \lfloor\lfloor a \|_n\|_n\|_n\|_n\|_n\|_n\|_n\|_n\|_n\).\)

The next step is to construct an element of \(\prod_{x : A \equiv B} \prod_{y : \| y \|_n} (c(x) \to y)\). Since the identity \(c(x) \to y\) is an \((n - 1)\)-type, it suffices to give an element of \(\prod_{x : A \equiv B} \prod_{y : \| x \|_n} (c(x) \to |a|_n)\). Since fibers are sum types, it suffices to give an element of \(\prod_{x : A \equiv B} \prod_{y : \| x \|_n} (c(x) \to |a|_n)\).

After swapping the first two products, the identity reduces by path induction to \(c(\lfloor a \|_n\|_n\|_n\|_n\|_n\|_n\|_n\|_n\|_n)\), for which we can use the reflexivity path.

\[\text{CONSTRUCTION 3.9.7. Let } g : A \to X \text{ and } h : X \to B, \text{ and let } \tilde{g} : A \to \sum_{b : B} h^{-1}(b) \text{ be the composition of } g \text{ with the canonical equivalence } X \to \sum_{b : B} h^{-1}(b) \text{ from Lemma 2.25.2. Thus } \tilde{g}(a) \equiv (h(g(a)), (a), \text{refl}_{h(g(a)))} \text{ for each } a : A, \text{ and the situation is visualized in the following diagram:}\]

\[
\begin{array}{c}
A \\
\downarrow \tilde{g} \quad \downarrow h \\
\sum_{b : B} h^{-1}(b) \\
\end{array}
\]

Then we have equivalences \(e(b) : (h g)^{-1}(b) \to \sum_{y : h^{-1}(b)} \tilde{g}^{-1}(b, y)\) for all \(b : B\).

\[\text{Implementation of Construction 3.9.7. Let, for each } b : B, e(b) \text{ map any pair } (a, p) : (h g)^{-1}(b) \to ((g(a), p), (a, q)). \text{ Here } g \text{ is of type } (b, g(a), p) \to (h(g(a)), g(a), \text{refl}_{h(g(a)))} \text{ and is given componentwise by } p : b \to h(g(a)), \text{refl}_{g(a)}\text{, and by the easy path over } p \text{ from } \text{refl}_{h(g(a))} \text{ in the identity type family } _{-} \to h(g(a)). \text{ This construction uses Definition 2.10.1, Definition 2.7.3, and Exercise 2.14.4(3).}\]

\[\text{Exercise 3.9.8. Complete the details of Construction 3.9.7. In particular, prove that } e \text{ is a fiberwise equivalence. Alternatively, construct your own } e \text{ by using Corollary 2.9.11 (twice!).}\]

\[\text{Exercise 3.9.9. Let } X \text{ be a type and let } Y(x) \text{ be a type for all } x : X. \text{ Construct an equivalence between } \|\sum_{x : X} Y(x)\|_n \text{ and } \|\sum_{y : Y} \|Y(x)\|_n\|_n.\]

We shall show in Theorem 3.9.11 that the \(n\)-image factorization of \(f : A \to B\) in Eq. (3.9.2) is unique. This result is called the \textit{universal property of the \(n\)-image}. We start by defining a convenient abbreviation.

\[\text{Definition 3.9.10. Let } X \text{ and } Y \text{ be types. For any } f : X \to Y \text{ we define the type } \text{Fact}(f) \text{ of factorizations of } f \text{ as follows:}\]

\[\text{Fact}(f) \equiv \sum_{Z : Z} \sum_{g : X \to Z} \sum_{h : Z \to Y} f \to h \circ g\]

\[\text{Theorem 3.9.11. Let } f : A \to B \text{ and } n \geq -2. \text{ Then the following type of factorizations of } f \text{ through its } n\text{-image is contractible:}\]

\[\sum_{(C, g, h, p) : \text{Fact}(f)} \text{isoConn}(g) \times \text{isoTrunc}(h).\]

\[\text{Proof. As the center of contraction we take } (\text{im}_n(f), p, i, \text{refl}_f, !)), \text{ with } p \text{ and } i \text{ as in Eq. (3.9.2). We can use } \text{refl}_f : f \to ip \text{ since } \text{fst}(p(a)) \equiv f(a) \text{ for all } a : A.\]
Let $X$ be a type and assume we are given an $n$-connected function $g : A \to X$ and an $n$-truncated function $h : X \to B$ and an identification $y : f \simeq hg$. Our task is then to construct an equivalence $e : \text{im}_n(f) \to X$ and to give identifications represented by the left and the right triangle in Fig. 3.13, that is, of types $g \overset{\sim}{\to} ep$ and $i \overset{\sim}{\to} he$. Then the factorization $(X, g, h, s, \ell)$ can be identified with the center of contraction by standard transport lemmas.

To simplify these constructions, we are going to replace $g$ and $h$ by projection maps. In view of Construction 3.9.7, we may assume without loss of generality that $X \equiv \bigwedge b : B P(b)$ for some family of $n$-types $P(b)$, and $h \equiv \text{id}$.

By Lemma 2.25.2 we may also assume without loss of generality that $A \equiv \bigwedge b : B \bigwedge r : P(b) Q(b, y)$, where $Q(b, y) \equiv g^{-1}(b, y)$ are the fibers of $g$, which are all $n$-connected by assumption. Define $R(b) \equiv \bigwedge r : P(b) Q(b, y)$ for all $b : B$. With $A \equiv \bigwedge b : B R(b)$, the function $g$ takes the form of the projection map $(b, y, q) \mapsto (b, y)$, as shown in Fig. 3.14. Using $s : f \simeq hg$ we get an identification of $f$ with the first projection, and an equivalence between its $n$-image and $\bigwedge b : B \| R(b) \|_n$. The $n$-connected map $p$ then takes the form $(b, y, q) \mapsto (b, (y, q)\|_n)$ as shown in Fig. 3.14.

Since $(\bigwedge b : B 1) \overset{s}{\to} B$ via $\text{fst}$, each type in Fig. 3.14 can be considered to be the sum of a type family parametrized by $b : B$. For constructing the equivalence $e$ that makes Fig. 3.14 commute, it suffices to construct for each $b : B$ the equivalence $e_b$ such that Fig. 3.15 commutes. Then we obtain $e$ as desired by summing over $B$, that is, by putting $e(b, z) \equiv (b, e_b(z))$ for all $b : B$ and $z : \| R(b) \|_n$.

Now let $b : B$. We have $\| R(b) \|_n \equiv \| \bigwedge r : P(b) Q(b, y) \|_n$. Since $P(b)$ is an $n$-type by assumption, we have the canonical equivalence of type $\| \bigwedge r : P(b) Q(b, y) \|_n \to \bigwedge r : P(b) \| Q(b, y) \|_n$ defined by mapping $(y, q)\|_n$ to $(y, |q|\|_n)$ (cf. Exercise 3.9.9). Since $Q(y, b)$ is $n$-connected for each $y : P(b)$ by assumption, so that $\| Q(b, y) \|_n$ is contractible, we also have the canonical equivalence $\text{fst} : \| \bigwedge r : P(b) Q(b, y) \|_n \to P(b)$. The composite of these two equivalences is $e_b$.

Finally, the identifications of type $g \overset{\sim}{\to} ep$ and $i \overset{\sim}{\to} he$, represented by the left and right triangle in Fig. 3.14, can also be constructed pointwise for every $b : B$, that is, in Fig. 3.15. Indeed, we have $e_b|\|_n \equiv \text{fst}$ for the left triangle, and the right triangle commutes trivially.

For the rest of this section, fix some natural number $m > 0$. As for our promised application, we consider the fibers of the $m^{th}$ root map $\rho_m$. On infinite cycles, this is equivalent to the degree $m$ map of the circle by Exercise 3.8.7, so we have a map $\_ m : \text{Cyc}_0 \to \text{Set}$, which we identify with the family $R_m : S^1 \to \text{Set}$ (Definition 3.6.7) by precomposing with the equivalence $c : S^1 \to \text{Cyc}_0$ from Theorem 3.5.6. For every infinite cycle $(X, t)$, the set $X/m$ has $m$ elements, and the (−1)-image is readily identified with $\text{FinSet}_m$, the groupoid of $m$-element sets (Definition 2.24.5). But what is the 0-image? The following theorem identifies the 0-image of $X/m$ with $\text{Cyc}_m$.

**Theorem 3.9.12.** The 0-image factorization of the map $\_ m : \text{Cyc}_0 \to \text{Set}$ consists of the type $\text{Cyc}_m$ and maps $q : \text{Cyc}_0 \to \text{Cyc}_m$ and $r : \text{Cyc}_m \to \text{Set}$. The map $q$ sends any infinite cycle $(X, t)$ to the $m$-cycle $(X/m, \vec{t})$, where...
The function \( f \colon \text{Cyc}_n \to A \) is contractible. Hence we first need to construct a function \( f \colon \text{Cyc}_n \to A \) together with an identification \( p : a \xrightarrow{\sim} f(pt_n) \) such that \( \text{ap}_f(\sigma_n)p = p\sigma \), see the diagram in the margin.

---

**Exercise 3.9.13.** Complete the details of the proof above.

**Exercise 3.9.14.** Let \( d \) be any order and let \( \rho_m : \text{Cyc}_d \to \text{Cyc}_{md} \) be the restriction of the \( m \)-th root map to \( \text{Cyc}_d \). Define \( \sim / m : \text{Cyc}_{md} \to \text{Set} \) as the family of fibers of \( \rho_m \). Show that the \( 0 \)-image factorization of \( \sim / m \) goes via \( \text{Cyc}_m \) by lifting \( \sim / m \) to \( q : \text{Cyc}_{md} \to \text{Cyc}_{mc} \). In particular, show that the preimage of \( q \) at the standard \( m \)-cycle can be identified with \( \text{Cyc}_d \).

---

### 3.10 Universal property of \( \text{Cyc}_n \)

Fix a natural number \( n > 0 \) and recall the definition of \( \text{Cyc}_n \) from Definition 3.8.1. This section is devoted to showing that maps out of \( \text{Cyc}_n \) into a groupoid \( A \) are given by the choice of a point together with a symmetry of order \( n \): any map \( \text{Cyc}_n \to A \) is uniquely determined by a point \( a : A \) together with a symmetry \( \sigma : a \xrightarrow{\sim} a \) such that \( \text{refl}_a = \sigma^n \).

Recall that \( \text{Cyc}_n \) contains the point \( pt_n \equiv (s, n) \), i.e., the standard \( n \)-cycle. This point has a symmetry \( \sigma_n \equiv (s^{-1}, !) \) whose second projection is a proof that \( ss^{-1} = s^{-1}s \). Recall also from Corollary 3.6.16 that all symmetries of \( pt_n \) are of the form \( \sigma_i \) for \( i = 0, \ldots, n - 1 \).

Given a groupoid \( A \), and a map \( f : \text{Cyc}_n \to A \), one can consider \( f(pt_n) : A \) and \( \text{ap}_f(\sigma_n) : f(pt_n) \xrightarrow{\sim} f(pt_n) \). Proofs of the equation \( \text{refl}_{pt_n} = \sigma^n \) in the set \( pt_n \xrightarrow{\sim} pt_n \) are mapped by \( \text{ap}_f \) to proofs of \( \text{refl}_{f(pt_n)} = \text{ap}_f(\sigma_n)^n \). Hence, the following map is well defined:

\[
ev_{n,A} : (\text{Cyc}_n \to A) \to \sum_{a : A} \sum_{\sigma : a \xrightarrow{\sim} a} \text{refl}_a = \sigma^n, \quad f \mapsto (f(pt_n), \text{ap}_f(\sigma_n), !).
\]

**Theorem 3.10.1.** For any groupoid \( A \), the map \( \ev_{n,A} \) above is an equivalence.

**Proof.** Let \( a : A \) and \( a : a \xrightarrow{\sim} a \) be such that \( \text{refl}_a = \sigma^n \) holds. We want to prove that the fiber

\[
\sum_{f : \text{Cyc}_n \to A} (a, \sigma, !) \xrightarrow{\sim} \ev_{n,A}(f)
\]

is contractible. Hence we first need to construct a function \( f : \text{Cyc}_n \to A \) together with an identification \( p : a \xrightarrow{\sim} f(pt_n) \) such that \( \text{ap}_f(\sigma_n)p = p\sigma \), see the diagram in the margin.
In order to do so, we will construct a function \( f : \text{Cyc}_n \to A \) together with a family of functions \( \hat{\rho}_x : (pt_n \xrightarrow{\sim} x) \to (a \xrightarrow{\sim} f(x)) \), parametrized by \( x : \text{Cyc}_n \), satisfying \( \hat{\rho}_x (\tau \circ a_n) = \hat{\rho}_x (\tau) \circ \sigma \) for all \( \tau : pt_n \xrightarrow{\sim} x \). By setting \( p \equiv \hat{\rho}_n (\text{refl}_{pt_n}) \), we will then have succeeded.

Let’s explain why the above indeed suffices. First, a simple path induction on \( a : x \xrightarrow{\sim} x' \) shows that \( \text{ap}_f(a) \hat{\rho}_{x'}(\_ \_ \_ LO) = \hat{\rho}_x(a) \). On the other hand, instantiating the condition on \( \hat{\rho} \) with \( x \equiv pt_n \) proves that \( \hat{\rho}_n (\tau \circ a_n) = \hat{\rho}_n (\tau) \circ \sigma \) for all \( \tau : pt_n \xrightarrow{\sim} pt_n \). This leads to the chain of equations:

\[
\text{ap}_f(a_n) p \equiv \text{ap}_f(a_n) \hat{\rho}_n (\text{refl}_{pt_n}) = \hat{\rho}_n (a_n \text{refl}_{pt_n}) = \hat{\rho}_n (a_n) \sigma \equiv p \sigma
\]

This shows that \( \hat{\rho} \) suffices.

It remains to construct the promised \( f \) and \( \hat{\rho} \). For each \( x : \text{Cyc}_n \), consider the type (with the product part visualized in the margin)

\[
T(x) \equiv \sum_{b : A} \sum_{n : (pt_n \xrightarrow{\sim} x)} \prod_{\tau : pt_n \xrightarrow{\sim} x} \tau (a_n) = (a \xrightarrow{\sim} b) n \sigma.
\]

We claim that \( T(x) \) is contractible for each \( x : \text{Cyc}_n \). We then get \( f(x) \), \( \hat{\rho}_x \) as well as the proof that \( \hat{\rho}_x \) has the desired property as the three components of the center of contraction, respectively.

To prove that \( T(x) \) is contractible for all \( x \) in the connected type \( \text{Cyc}_n \), it is enough to prove it for \( x \equiv pt_n \). First, the equivalence \( i \mapsto a_n^i \) of type \( n \xrightarrow{\sim} (pt_n = pt_n) \) induces an equivalence of type

\[
T(pt_n) \xrightarrow{\sim} \sum_{b : A} \sum_{n : (pt_n \xrightarrow{\sim} b)} \prod_{k : n} \tau (s(k)) = (a \xrightarrow{\sim} b) n \sigma.
\]

Now, note that any \( \tau : n \to (a \xrightarrow{\sim} b) \) such that \( \tau (s(k)) = \tau (k) \sigma \) for all \( k : n \) is entirely determined by \( \tau (0) \), as then \( \tau (i) = \tau (0) \sigma^i \) for all \( i : n \). Moreover, any path \( q \) in \( a \xrightarrow{\sim} b \) defines a function \( \pi_q : i \mapsto q \sigma^i \) which satisfies \( \pi_q (0) = q \) and \( \pi_q (s(k)) = \pi_q (k) \sigma \) for all \( k : n \). Thus, evaluation at \( 0 \) is an equivalence

\[
\text{ev}_0 : \left( \sum_{\tau : n \to (a \xrightarrow{\sim} b)} \prod_{k : n} \tau (s(k)) = (a \xrightarrow{\sim} b) n \sigma \right) \xrightarrow{\sim} (a \xrightarrow{\sim} b), \quad \text{ev}_0 (\tau, l) \equiv \tau (0).
\]

The equivalence \( \text{ev}_0 \) induces an equivalence of type

\[
T(pt_n) \xrightarrow{\sim} \left( \sum_{b : A} a \xrightarrow{\sim} b \right)
\]

and hence \( T(pt_n) \) is contractible. This completes the construction of the center of contraction of the fiber \( \text{ev}_0^A (a, \sigma, !) \).

Finally, we prove that the fiber \( \text{ev}_0^A (a, \sigma, !) \) is a proposition. Let \( (f, p, !) \) and \( (f', p', !) \) be two elements of the fiber. We want to identify them. From the proofs in their third components we infer \( \text{ap}_p \circ p^{-1} = \text{ap}_f (a_n) \) and \( \text{ap}_{p'} \circ p'^{-1} = \text{ap}_f (a_n) \), respectively. Define the family of sets \( U(x) \equiv (f(x) \xrightarrow{\sim} f'(x)) \) parametrized by \( x : \text{Cyc}_n \). It suffices to find a \( \chi : \prod_{x : \text{Cyc}_n} U(x) \) such that the diagram in the margin commutes.

The element \( \tau \equiv p' \circ p^{-1} : U(pt_n) \) is peculiar in that \( \text{trp}^U_\chi (\tau) = \tau \) for all \( q : pt_n \xrightarrow{\sim} pt_n \). Indeed, we use once again that symmetries of \( pt_n \) in \( \text{Cyc}_n \) are of the form \( a_n^i \) and we calculate:

\[
\text{trp}^U_{a_n^i} (\tau) = \text{ap}_f (a_n^i) \cdot \tau \cdot \text{ap}_f (a_n^i)^{-1} = p' \sigma^i p'^{-1} \tau p \sigma^{-1} p^{-1} = p' \circ p^{-1}
\]

The construction of \( f \) is really a special case of the delooping of the abstract group homomorphism \( a_n^i \mapsto \sigma^i \) in Section 4.10.

\[
\begin{align*}
\text{ev}_0 : & \left( \sum_{\tau : n \to (a \xrightarrow{\sim} b)} \prod_{k : n} \tau (s(k)) = (a \xrightarrow{\sim} b) n \sigma \right) \xrightarrow{\sim} (a \xrightarrow{\sim} b), \quad \text{ev}_0 (\tau, l) \equiv \tau (0). \\
\text{ap}_p \circ p^{-1} & = \text{ap}_f (a_n), \\
\text{ap}_{p'} \circ p'^{-1} & = \text{ap}_f (a_n). \\
\end{align*}
\]
Now it is easy to prove that the following type is contractible:

\[ V(x) \equiv \sum_{\alpha : U(x)} \prod r : pt_n \mapsto x \alpha = \text{trp}_r^{\chi}(\tau) \]

To do so, we use the connectedness of \( \text{Cyc}_n \) and verify the contractibility of \( V(pt_n) \). Clearly, \((\tau, !)\) is a center of contraction by the peculiarity of \( \tau \). Also, if \( \alpha \) and \( \beta \) are elements of \( V(pt_n) \), then \( \alpha = \beta \) by taking \( r \equiv \text{refl}_{pt_n} \). Now \( \chi \) is defined as the function mapping \( x \) to the center of contraction of \( V(x) \), so that \( \chi(pt_n) = \tau \) as we wanted. □

As a direct corollary, we can classify the connected set bundles over \( \text{Cyc}_n \) for finite orders \( n \). Indeed, the corresponding families \( S : \text{Cyc}_n \to \text{Set} \) are precisely those cycles \((X, t)\) with \( t^n = \text{id} \), i.e., whose order divides \( n \). If we restrict to decidable connected set bundles, equivalently, decidable cycles, these are the usual finite cycles with order dividing \( n \).

### 3.11 Getting our cycles in order

**TODO:** Exposition and figures

**Exercise 3.11.1.** Prove that if \((X, t), (Y, u)\) are cycles, \( x_0 : X \), then the type of maps \( f : (X, t) \to (Y, u) \) is equivalent to \( P \times Y \), where \( P \equiv (\text{ord}(u) \mid \text{ord}(t)) \equiv (H_f \subseteq H_u) \).

Thus, an order \( p \) divides an order \( q \) if and only if there is a map of cycles from a cycle of order \( q \) to a cycle of order \( p \).

**Theorem 3.11.2.** The partially ordered set \((\text{Order}, \mid)\) is a lattice with least element the finite order 1 and greatest element the infinite order, represented by the number 0, and meets and joins given by “gcd” and “lcm”, respectively.

- Subgroups of \( C_n : C_k \) where \( k \mid n \), connected set bundles of \( \text{Cyc}_n \).

### 3.11.3 More TODO

- Classify connected set bundles over \( \text{Cyc}_n \).
- Universal property of \( \text{Cyc}_n \) among groupoids.
- Bijective proof of \( mn = \text{lcm}(m, n) \times \text{gcd}(m, n) \) via the product of cycles.
- Chinese remainder stuff.
- Somehow sneak in totatives and automorphisms of cyclic groups?
An identity type is not just any type: in the previous sections we have seen that the identity type \( a \sim_A a \) reflects the “symmetries” of an element \( a \) in a type \( A \). Symmetries have special properties. For instance, you can rotate a square by 90°, and you can reverse that motion by rotating it by −90°. Symmetries can also be composed, and this composition respects certain rules that holds in all examples. One way to study the concept of “symmetries” would be to isolate the common rules for all our examples, and to show, conversely, that anything satisfying these rules actually is an example.

With inspiration of geometric and algebraic origins, it became clear to mathematicians at the end of the 19th century that the properties of such symmetries could be codified by saying that they form an abstract group. In Section 2.5 we saw that equality is “reflexive, symmetric and transitive” – implemented by operations \( \text{refl}_a, \text{symm}_{a,b} \) and \( \text{trans}_{a,b,c} \), and an abstract group is just a set with such operations satisfying appropriate rules.

We attack the issue more concretely: instead of focusing on the abstract properties, we bring the type exhibiting the symmetries to the fore. The axioms for an abstract group follow from the rules for identity types, without us needing to impose them. We will show that the two approaches give the same end result.

In this chapter we lay the foundations and provide some basic examples of groups.

4.1 Brief overview of the chapter

In Section 4.2 we give the formal definition of a group along with some basic examples. In Section 4.3 we spell out the details, expanding on the properties of the identity type of a group and comparing these properties with those of an abstract group. We then return in Section 4.4 to groups more generally, explaining how these map to each other through “homomorphisms” (which to us are simply given by pointed maps), and what this entails for the identity types: all the abstract group properties are preserved. As an important example, we study the sign homomorphism in Section 4.5.

In most of our exposition we make the blanket assumption that the identity type in question is a set, but in Section 4.6 we briefly discuss \( \infty \)-groups, where this assumption is dropped.

Classically, groups have appeared because they “act” on a set (or more general objects), that is to say, they collect some of the symmetries of the set. This is a point of view that we will return to many times and we give
the basic theory in Section 4.7. This section should remind the reader of the material in Chapter 3, where we dealt with the special case of the group of integers. More generally, connected set bundles now reappear in the guise of “transitive $G$-sets”, laying the groundwork for our later discussion of the set of subgroups of a group.

Another important notion, also discussed in Section 4.7, is the type of “$G$-torsors”, which at first glance can appear frightening. However, a $G$-torsor corresponds to a universal set bundle, and the important step is to consider the type of these. The type of $G$-torsors recovers the underlying classifying type of the group $G$, and this idea is used in Section 4.9 to build the equivalence between our definition of a group and the abstract version taught in most algebra classes. This is followed up for homomorphisms in Section 4.10 and for $G$-sets in Section 4.13.

With all this in place, the structure of the type of groups is in many aspects similar to the universe, in the sense that many of the constructions on the universe that we’re accustomed to have analogues for groups, namely: functions are replaced by homomorphisms; products stay “the same,” as we will see in Example 4.2.23 (and more generally, product types over sets “stay the same”); and the sum of two groups has a simple implementation as the sum of the underlying types with the base points identified, as defined more precisely in Definition 4.16.1. In the usual treatment this is a somewhat more difficult subject involving “words” taken from the two groups. This reappears in our setting when we show that homomorphisms from a sum to another group correspond to pairs of homomorphisms (just as for sums of types and functions between types).

A deeper study of subgroups is postponed to Chapter 5, where they take center stage.

### 4.2 The type of groups

Recall the definition of pointed types, Definition 2.21.1, and the related conventions established in Section 2.21.

**Definition 4.2.1.** Given a pointed type $X \equiv (A, a)$, we define its type of loops by $\Omega X \equiv (a \to A \cdot a)$.

**Example 4.2.2.** We defined the circle $S^1$ in Definition 3.1.1 by declaring that it has a point $\cdot$ and an identification (“symmetry”) $\circ : (\cdot \Rightarrow \cdot) \equiv \Omega(S^1, \cdot)$, and we proved in Corollary 3.4.6 that $\Omega(S^1, \cdot)$ is equivalent to the set $\mathbb{Z}$ (of integers), where $n \in \mathbb{Z}$ corresponds to the $n$-fold composition of $\circ$ with itself (which works for both positive and negative $n$). We can think of this as describing the symmetries of $\cdot$: we have one “generating symmetry” $\circ$, and this can be applied any number of times, giving a symmetry for each number. Composition of loops here corresponds to addition of integers.

The circle is an efficient packaging of the “group” of integers, for the declaration of $\cdot$ and $\circ$ not only gives the set $\mathbb{Z}$ of integers, but also the addition operation.

**Example 4.2.3.** Recall the finite set $2 : \text{FinSet}_2$ from Definition 2.24.1, containing two elements. According to Exercise 2.13.3, the identity type $2 \Rightarrow 2$ has exactly two distinct elements, $\text{refl}_2$ and twist, and doing twist...
twice yields refl₂. We see that these are all the symmetries of a two point set you’d expect to have: you can let everything stay in place (refl₂); or you can swap the two elements (twist). If you swap twice, the result leaves everything in place. The pointed type FinSet₂ (of “finite sets with two elements”), with 2 as the base point, is our embodiment of these symmetries, i.e., they are the elements of \( \Omega(\text{FinSet}_2, 2) \).

Observe that (by the definition of \( S^1 \)) there is an interesting function \( S^1 \to \text{FinSet}_2 \), sending \( \cdot : S^1 \) to \( 2 : \text{FinSet}_2 \) and \( \cup \) to twist. We saw this already in Fig. 3.2.

If we take the type of loops \( \Omega(A, a) = (a \xrightarrow{\alpha} A a) \) for some type \( A \) and some element \( a : A \) we get the notion of an \( \infty \)-group, cf. Section 4.6 below. However, in elementary texts it is customary to restrict the notion of a group to the case when \( a \xrightarrow{\alpha} A a \) is a set, as we will do, starting in Section 4.3. This makes some proofs easier, since if we are given two elements \( g, h : a \xrightarrow{\alpha} A a \), then the identity type \( g \sim h \) is a proposition (and we can simply write \( g = h \), i.e., \( g \) can be equal to \( h \) in at most one way. Hence questions relating to uniqueness of proofs of equality will never present a problem.

The examples of groups that Klein and Lie were interested in often had more structure on the set \( \Omega(A, a) \), for instance a smooth structure. For such groups it makes sense to look at smooth maps from the real numbers to \( \Omega(A, a) \), but absent the existence and choice of such an \( S \)-space, we saw this already in Fig. 3.2.

Remark 4.2.4. The reader may wonder about the status of the identity type \( a \xrightarrow{\alpha} A a' \) where \( a, a' : A \) are different elements. One problem is of course that if \( p, q : a \xrightarrow{\alpha} A a' \), there is no obvious way of composing \( p \) and \( q \) to get another element in \( a \xrightarrow{\alpha} A a' \), and another is that \( a \xrightarrow{\alpha} A a' \) does not have a distinguished element, such as \( \text{refl}_a : a \xrightarrow{\alpha} A a \). Given \( f : a \xrightarrow{\alpha} A a' \) we can use transport along \( f \) to compare \( a \xrightarrow{\alpha} A a' \) with \( a \xrightarrow{\alpha} A a \) (much as affine planes can be compared with the standard plane or a finite dimensional real vector space is isomorphic to some Euclidean space), but absent the existence and choice of such an \( f \) the identity types \( a \xrightarrow{\alpha} A a' \) and \( a \xrightarrow{\alpha} A a \) are different animals. We will return to this example after we have defined torsors.

Remark 4.2.5. As a consequence of Lemma 2.20.4, the inclusion of the component \( A_{(a)} \equiv \sum_{x : A} \| a \xrightarrow{x} \| \) into \( A \) (i.e., the first projection) induces an equivalence of identity types from \( (a, !) \xrightarrow{\alpha} A_{(a)} (a, !) \) to \( a \xrightarrow{\alpha} A a \), and thus from \( \Omega(A_{(a)} (a, !)) \) to \( \Omega(A, a) \). This means that, when considering the loop type \( \Omega(A, a) \), “only the elements \( x : A \) with \( x \) merely equal to \( a \) are relevant”, and to avoid irrelevant extra components, we should consider only connected types \( A \) (cf. Definition 2.16.8).

Also, our preference for \( \Omega(A, a) \) to be a set indicates that we should consider only the connected types \( A \) that are groupoids.

Definition 4.2.6. The type of pointed, connected groupoids is the type

\[
\mathcal{U}^{\leq 1} := \sum_{A : \text{Grpd}} (A \times \text{isConn}(A) \times \text{isGrpd}(A)).
\]

Exercise 4.2.7. Show that a pointed type \((A, a)\) is connected if and only if the type \( \prod_{x : A} \| a \xrightarrow{x} \| \) has an element. Show that a connected pointed

The meaning of the superscript “\( = 1 \)” can be explained as follows: We also define

\[
\mathcal{U}^{\geq 1} := \sum_{A : \text{Groupoid}} \text{isGrpd}(A)
\]

and

\[
\mathcal{U}^{\geq 0} := \sum_{A : \text{Set}} \text{isConn}(A)
\]

to emphasize that groupoids are 1-types; the type of connected types is defined as follows.

\[
\mathcal{U}^{\geq 2} := \sum_{A : \text{Set}} \text{isConn}(A)
\]

Similar notations with a subscript “\( s \)” indicate pointed types.
type $X$ is a groupoid if and only if the type $\Omega X$ is a set. Conclude by showing that the type $\mathcal{U}^{-1}$ is equivalent to the type

$$
\sum_{A: \mathcal{U}} \sum_{a:A} \left( \left( \prod_{x:A} a \xrightarrow{\sim} A x \right) \times \text{isSet}(\Omega(A,a)) \right).
$$

Remark 4.2.8. We shall refer to a pointed connected groupoid $(A, a, p, q)$ simply by the pointed type $X \equiv (A, a)$. There is no essential ambiguity in this, for the types $\text{isConn}(A)$ and $\text{isGrpd}(A)$ are propositions (Lemma 2.15.4 and Lemma 2.15.7), and so the witnesses $p$ and $q$ are unique.

We also write $\text{pt}_X$ for the base point $a$ of the pointed type $X$, as in Definition 2.21.1.

We are now ready to define the type of groups.

Definition 4.2.9. The type of groups is a wrapped copy (see Section 2.12.8) of the type of pointed connected groupoids $\mathcal{U}^{-1}$,

$$
\text{Group} \equiv \text{Copy}_{\mathcal{U}}(\mathcal{U}^{-1}),
$$

with constructor $\Omega: \mathcal{U}^{-1} \to \text{Group}$. A group is an element of Group.

Definition 4.2.10. We write $B: \text{Group} \to \mathcal{U}^{-1}$ for the destructor associated with $\text{Copy}_{\mathcal{U}}(\mathcal{U}^{-1})$. For $G: \text{Group}$, we call $BG$ the classifying type of $G$.

Moreover, the elements of $BG$ will be referred to as the shapes of $G$, and we define the designated shape of $G$ by setting $\text{sh}_G \equiv \text{pt}_{BG}$, i.e., the designated shape of $G$ is the base point of its classifying type.

Definition 4.2.11. Let $G$ be a group. We regard every group as a group of symmetries, and thus we refer to the elements of $\Omega BG$ as the symmetries in $G$; they are the symmetries of the designated shape $\text{sh}_G$ of $G$. (Notice the careful distinction between the phrases “symmetries in” and “symmetries of”.) We adopt the notation $UG$ for the type $\Omega BG$ of symmetries in $G$; it is a set.

Remark 4.2.12. We are emphasizing that the essential feature of a group is the symmetries of its designated shape. That is why we defined Group to be a copy of $\mathcal{U}^{-1}$, and not $\mathcal{U}^{-1}$ itself; the type $UG$ is at least as important as $BG$ – the copying forces us to use the notation $BG$, preventing a glib identification of $G$ with its classifying type. As noted in Section 2.12.8, the constructor and destructor pair forms an equivalence $G \cong U^{-1}$. The type $\mathcal{U}^{-1}$ is a subtype of $\mathcal{U}$, so once you know that a pointed type $X$ is a connected groupoid, you know also that $X$ is the classifying type for a group, namely $G : \equiv \Omega X$.

Note that the equivalence also entails that identifications (of groups) of type $G \overset{\sim}{\to} H$ are equivalent to identifications (of pointed types) of type $BG \cong BH$.

Remark 4.2.13. To define a function $f: \prod_G: \text{Group} T(G)$, where $T(G)$ is a type family parametrized by $G: \text{Group}$, it suffices to consider the case $G : \equiv \Omega X$, where $X$ is a pointed connected groupoid, namely the classifying type $BG$.

Frequently we want to consider the symmetries $\Omega(A, a)$ of some element $a$ in some groupoid $A$, so we introduce the following definition.

---

4 As a notational convention we always write the “$B$” so that it sits next to and matches the shape of its operand. You see immediately the typographical reason behind this convention: The italic letters $B, G$ and $\Omega$ get along nicely, while the roman $B$ would clash with its italic friend $G$ if we wrote $BG$ instead.

5 Taking the symmetries in a group thus defines a map $U: \text{Group} \to \text{Set}$, with $UX \to \Omega X$. Just as with “$B$”, we write the “$U$” so that it matches the shape of its operand.

Recall also the example of the negated natural numbers $\mathbb{N}^\bot$ from Section 2.12.8: Its elements are $n: \mathbb{N}$, for $n: \mathbb{N}$ to remind us of $0$ and $1$.

6 If you are bothered by the convention to write the classifying type of $G$ in italic like a variable, you can either think of $BG$ as a locally defined variable denoting the classifying type that is defined whenever a variable $G$ of type $\text{Group}$ is introduced, or you can imagine that whenever such a $G$ is introduced (with the goal of making a construction or proving a proposition), we silently apply the induction principle to reveal a wrapped variable $BG: \Omega^{-1}$. 

**Definition 4.2.14.** For a groupoid $A$ with a specified point $a$, we define the automorphism group of $a : A$ by

$$\text{Aut}_A(a) \equiv \Omega(A(a), (a, !)),$$

i.e., $\text{Aut}_A(a)$ is the group with classifying type $\text{BAut}_A(a) \equiv (A(a), (a, !))$, the connected component of $A$ containing $a$, pointed at $a$.

**Remark 4.2.15.** For any $G \equiv \Omega(A, a) : \text{Group}$, we have an identification $G \xrightarrow{\sim} \text{Aut}_A(a)$, because we have an identification of pointed types $(A(a), (a, !)) \xrightarrow{\sim} (A, a)$, since $A$ is connected.

In other words, for any $G \equiv \Omega BG$, we have an identification $G \xrightarrow{\sim} \text{Aut}_{BG}(\text{sh}_G)$, of $G$ with the automorphism group of the designated shape $\text{sh}_G : BG$.

4.2.16 First examples

**Example 4.2.17.** The circle $S^1$, which we defined in Definition 3.1.1, is a connected groupoid (Lemma 3.1.6, Corollary 3.4.6) and is pointed at $\bullet$.

The identity type $\bullet \xrightarrow{\sim} S^1$ is equivalent to the set of integers $\mathbb{Z}$ and composition corresponds to addition. This justifies our definition of the group of integers as

$$\mathbb{Z} \equiv \Omega(S^1, \bullet).$$

Recall from Remark 4.2.15 that there is then a canonical identification of type $\mathbb{Z} \xrightarrow{\sim} \text{Aut}_{S^1}(\bullet)$. In other words, the classifying type of $\mathbb{Z}$ is $\text{BZ} \equiv S^1$, pointed at $\bullet$. It is noteworthy that along the way we gave several versions of the circle, each of which has its own merits, with the type of infinite cycles from Definition 3.5.3,

$$\text{InfCyc} \equiv \left( \sum_{X : \mathcal{U}} (X \rightarrow X) \right) \xrightarrow{\sim} \sum_{X : \mathcal{U}} \sum_{t : X \rightarrow X} ||(Z, s) \xrightarrow{\sim} (X, t)||$$

being a very convenient one. It gives a very useful identification of type $\mathbb{Z} \xrightarrow{\sim} \text{Aut}_{\text{Cyc}}(Z, s)$.

**Example 4.2.18.** Apart from the circle, there are some important groups that come almost for free: namely the symmetries in the type of sets.

1. Recall that the set $\mathbb{1}$ has the single element which we can call $\ast$. Then $\text{Aut}_{\mathbb{1}}(\ast)$ is a group called the trivial group. Of course, this is also $\text{Aut}_{\text{True}}(\text{triv})$, the automorphism group of the trivial element in the type True.

2. If $n : \mathbb{N}$, then the permutation group of $n$ letters (also known as the symmetric group of order $n$) is

$$\Sigma_n \equiv \Omega(\text{FinSet}_n, n),$$

where $\text{FinSet}_n$ is the groupoid of sets of cardinality $n$ (cf. 2.24.5). The classifying type is thus $\text{B}\Sigma_n \equiv (\text{FinSet}_n, n)$. With our convention of Remark 4.2.15, we can tolerate $\text{Aut}_{\text{FinSet}}(n)$, $\text{Aut}_{\text{Set}}(n)$, or even, by Remark 4.6.5, $\text{Aut}_{\mathcal{U}}(n)$ as synonyms for the group $\Sigma_n$ (recall that FinSet and Set are the subtypes of $\mathcal{U}$ of finite sets and sets, respectively).

If the reader starts worrying about size issues, see Remark 4.2.20.
(3) More generally, if $S$ is a set, is there a pointed connected groupoid $(A, a)$ so that $a \sim A a$ models all the “permutations” $S \xrightarrow{\sim} \text{Set } S$ of $S$? Again, the only thing wrong with the groupoid Set of sets is that Set is not connected. The group of permutations of $S$ is defined to be

$$\Sigma_S := \Omega(\text{Set}_S, S) \equiv \text{Aut}_{\text{Set}}(S),$$

with classifying type $\text{B} \Sigma_S := (\text{Set}_S, S)$.

**Exercise 4.2.19.** Using Definition 2.24.1 compare the definitions in Example 4.2.18, (2) and (3), and give identifications of type $\Sigma_n \xrightarrow{\sim} \Sigma_n$ for $n : \mathbb{N}$. Also show that $\Sigma_{\text{false}}$ and $\Sigma_{\text{true}}$ are trivial groups.

**Remark 4.2.20.** This remark is for those who worry about size issues—a theme we usually ignore in our exposition. If we start with a base universe $U_0$, the groupoid FinSet, of sets of cardinality $n$ is the $\Sigma$-type $\Sigma_A : U_0 \vdash \Sigma_n$ over $U_0$ and so (without any modification) will lie in any bigger universe $U_1$. In order to accommodate the permutation groups of sets in $U_0$, the universe “$\mathcal{U}$” appearing as a subscript of the first $\Sigma$-type in Definition 4.2.6, appearing later in the definition of “group”, needs to be at least as big as $U_1$. If $\mathcal{U}$ is taken to be $U_1$, then the type Group of groups will not be in $U_1$, but in some bigger universe $U_2$. If we then choose some group $G : \text{Group}$ and look at its group of automorphisms, $\text{Aut}_G(G)$, based on the identity type $G \xrightarrow{\sim} \text{Group } G$, this will be an element of Group only if the universe $\mathcal{U}$ in the definition of Group is at least as big as $U_2$. Our convention from Section 2.3 is that the universes form an ascending chain $U_0 \subseteq U_1 \subseteq U_2 \subseteq \ldots$, corresponding to which there will an ascending chain of types of groups,

$$\text{Group}_i \equiv \text{Copy}_\mathcal{U} ((\mathcal{U}_i)^{\omega_1}) : \mathcal{U}_{i+1},$$

and any group we encounter will be an element of Group$_i$ for $i$ large enough.

These matters concerning universes are nontrivial and important, but in this text we have chosen to focus on other matters.  

**Example 4.2.21.** In Corollary 3.6.16 we studied the symmetries of the standard $m$-cycle $(m, s)$ for $m$ a positive integer, and showed that there were $m$ different such symmetries. Moreover, we showed that these symmetries can be identified with the elements $0, 1, \ldots, m - 1$ of $m$ (according to the image of $0$), and under this correspondence composition of symmetries correspond to addition modulo $m$, with $0$ the identity. Note that all of these can be obtained from $1$ under addition. Corresponding, the cyclic group of order $m$ is defined to be

$$C_m := \Omega(\text{Cyc}_m, (m, s)) \equiv \text{Aut}_{\text{Cyc}}((m, s)),$$

with classifying type $\text{B}C_m := (\text{Cyc}_m, (m, s))$.

By using univalence on the equivalences of Theorem 3.3.8, we get a chain of identifications

$$C_m \longrightarrow \text{Aut}_{\Sigma X : \text{Set}(X \rightarrow X)}(m, s) \xrightarrow{\text{Symmetry}} \text{Aut}_{\text{Set}^\times}(S^\times, \delta_m) \longrightarrow \text{Aut}_{\text{Set}^\times}(R_m),$$

Note that the cyclic group of order 1 is the trivial group, the cyclic group of order 2 is equivalent to the symmetric group $\Sigma_2$: there is exactly one nontrivial symmetry $f$ and $f^2$ is the identity. When $m > 2$ the cyclic group of order $m$ is a group that does not appear elsewhere in our current list. In particular, the cyclic group of order $m$ has only $m$ different symmetries, whereas we will see that the group of permutations $\Sigma_m$ has $m! = 1 \cdot 2 \cdot \ldots \cdot m$ symmetries.
where $\delta_m : S^1 \to S^1$ is the degree $m$ map, and $R_m : S^1 \to \text{Set}$ is the $m$th power bundle from Definition 3.6.7.

For reasons that will become clear later (Definition 5.5.8), we introduce another name for the cyclic group of order $m$, corresponding to the last step above, namely,

$$\mathbb{Z}/m\mathbb{Z} \equiv \text{Aut}_{\text{FinSet}}(R_m).$$

**Example 4.2.22.** There are other (beside the symmetries of the $m$-cycle and of the $m$-fold set bundle) ways of obtaining the cyclic group of order $m$, which occasionally are more convenient. The prime other interpretation comes from thinking about the symmetries of the $m$-cycle in a slightly different way. We can picture the $m$-cycle as consisting of $m$ points on a circle, e.g., as the set of $m^{th}$ roots of unity in the complex plane, as shown in Fig. 4.1.

Any cyclic permutation is in particular a permutation of the $m$-element set underlying the cycle. This manifests itself as the projection map $\text{pr} : \text{Cyc}_m \to \text{FinSet}_m$ equivalently, using the notation introduced above, $\text{pr} : \text{BC} \to \Sigma_m$, where the group $\Sigma_m = \text{Aut}_{\text{FinSet}}(m)$ is that of all permutations of the set $m$. The projection map, whose fiber at $X : \Sigma_m$ is the set $\Sigma : X \to X || |(X, i) = (m, s)||$, captures $C_m$ as a “subgroup” of the permutations, namely the cyclic ones, corresponding to the fact that the shapes of $C_m$ (i.e., the elements of $\text{BC} \Sigma_m$) are those of $\Sigma_m$ together with the extra structure of the “cyclic ordering” determined by $f$.

But how do we capture the other aspect of $C_m$, mentioned in Example 4.2.21, that all the cyclic permutations can be obtained by a single generating one? When thinking of the $m$th roots of unity as in Fig. 4.1, we can take complex multiplication by $\xi$ to be the generating symmetry.

The key insight is provided by the function $R_m : S^1 \to \text{FinSet}_m$ from Definition 3.6.7, with $R_m(\cdot) \equiv m$ and $R_m(\cup) \equiv s$, picking out exactly the cyclic permutation $s : m \to m$ (and its iterates) among all permutations. Using our new notation, we can also write this as

$$R_m : \text{BZ} \to \Sigma_m.$$

Set truncation (Definition 2.24.4) provides us with a tool for capturing only the symmetries in $\text{FinSet}_m$ hit by $R_m$: the (in language to come) subgroup of the permutation group generated by the cyclic permutation $s$ is the group

$$C'_m \equiv \Omega(\text{BC}'_m, \text{sh}_{C'_m}),$$

where $\text{BC}'_m \equiv \Sigma_X : \text{FinSet}_m || R^{-1}_m(X)||0$ and $\text{sh}_{C'_m} \equiv (m, (\cdot, \text{refl}_m)|0)$. That is, $\text{BC}'_m$ is the 0-image of $R_m$ in the sense of Section 3.9, so is in particular a pointed connected groupoid. Since we have a factorization of $R_m$ as the equivalence $c : S^1 \to \text{Cyc}_0$ followed by the map $\sim / m : \text{Cyc}_0 \to \Sigma_m$, and since $\text{Cyc}_m$ is the 0-image of the latter by Theorem 3.9.12, we get a uniquely induced pointed equivalence $g : \text{BC}'_m \to \text{BC}_m$. This identifies the set $|| R^{-1}_m(X)||0$ with the set of cycle structures on the $m$-element set $X$.

**Example 4.2.23.** If you have two groups $G$ and $H$, their product $G \times H$ is given by taking the product of their classifying types:

$$G \times H \equiv \Omega(\text{BG} \times \text{BH}).$$

![Fig: m-cycle-roots](image-url)

**Figure 4.1:** The $m$-cycle as the $m$th roots of unity. (Here $\xi = e^{2\pi i/m}$ is a primitive $m$th root.)

10 In the terminology of Section 2.27, this map forgets the cycle structure on the underlying set.

11 More precisely, but using language not yet established: $C_m$ is both isomorphic to $\mathbb{Z}/m\mathbb{Z}$, the “quotient group” (cf. Definition 5.5.8) of $\mathbb{Z}$ by the “kernel” (cf. Definition 5.3.2) induced by $R_m$, and to $C'_m$, which is the corresponding “image” (cf. Section 5.3.10). This pattern will later be captured in Theorem 5.10.2.

12 Note that $\text{B}(G \times H) \equiv \text{BG} \times \text{BH}$ is pointed at $\text{sh}_{G \times H} \equiv (\text{sh}_G, \text{sh}_H)$. 
For instance, $\Sigma_2 \times \Sigma_2$ is called the Klein four-group or Vierergruppe, because it has four symmetries.

**Exercise 4.2.24.** Show that we cannot identify $C_4$ and $\Sigma_2 \times \Sigma_2$, i.e., the Klein four-group is not a cyclic group.

**Remark 4.2.25.** In Lemma 4.3.4 we will see that the identity type of a group satisfies a list of laws justifying the name “group” and we will later show that groups are uniquely characterized by these laws.

Some groups have the property that the order you perform the symmetries is immaterial. The prime example is the group of integers $\mathbb{Z} \equiv \Omega(S^1 \cdot \cdot)$, Any symmetry is of the form $\cup^n$ for some integer $n$, and if $\cup^m$, then $\cup^n \cup^m = \cup^{n+m} = \cup^m \cup^n$.

Such cases are important enough to have their own name:

**Definition 4.2.26.** A group $G$ is abelian if all symmetries commute, in the sense that the proposition

$$\text{isAb}(G) \equiv \prod_{g,h : UG} gh = hg$$

is true. In other words, the type of abelian groups is

$$\text{AbGroup} \equiv \sum_{G : \text{Group}} \text{isAb}(G).$$

**Exercise 4.2.27.** Show that symmetric group $\Sigma_2$ is abelian, but that $\Sigma_3$ is not. Show that if $G$ and $H$ are abelian groups, then so is their product $G \times H$.

We can envision $g$ commuting with $h$ in a group $A \equiv \Omega(A, a)$ by the picture in the margin; going from (upper left hand corner) $a$ to (lower right hand corner) $a$ by either composition gives the same result.

**Remark 4.2.28.** Abelian groups have the amazing property that the classifying types are themselves identity types (of certain 2-types). This can be used to give a very important characterization of what it means to be abelian. We will return to this point in Section 4.12.

Alternatively, the reference to $\text{isAb}$ in the definition of abelian groups is avoidable using the “one point union” of pointed types $X \vee Y$ of Definition 4.16.1 below. (It is the sum of $X$ and $Y$ where the base points are identified.) Exercise 4.16.6 offers the alternative definition that a group $G$ is abelian if and only if the “fold” map $BG \vee BG \to BG$ (where both summands are mapped by the identity) factors over the inclusion $BG \vee BG \to BG \times BG$, i.e., this turns out to be a proposition equivalent to $\text{isAb}(G)$.

**Exercise 4.2.29.** Let $\Omega(A, a) : \text{Group}$ and let $b$ be an arbitrary element of $A$. Prove that the groups $\Omega(A, a)$ and $\Omega(A, b)$ are merely identical, in the sense that $\|\Omega(A, a) = \Omega(A, b)\|$ is true. Similarly for $\infty$-groups when you get that far.

**Exercise 4.2.30.** Given two groups $G$ and $H$. Prove that $G \to H$ is a set. Prove that the type of groups is a groupoid. This means that, given a group $G$, the component of Group, containing (and pointed at) $G$, is again a group, $\text{Aut}_{\text{Group}}(G)$, which we will call more simply the group $\text{Aut}(G)$ of automorphisms of $G$, or the automorphism group of $G$. 

\[\text{Aut}(G)\]
4.3 Abstract groups

Studying the identity type leads one to the definition of what an abstract group should be. We fix a type \( A \) and an element \( a : A \) for the rest of the section, and we focus on the identity type \( a \mapsto a \). We make the following observations about its elements and operations on them.

1. There is an element \( \text{refl}_a : a \mapsto a \). (See page 15, item (E2).) We set \( e \equiv \text{refl}_a \) as notation for the time being.

2. For \( g : a \mapsto a \), the inverse \( g^{-1} : a \mapsto a \) was defined in Definition 2.5.1. Because it was defined by path induction, this inverse operation satisfies \( e^{-1} \equiv e \).

3. For \( g, h : a \mapsto a \), the product \( h \cdot g : a \mapsto a \) was defined in Definition 2.5.2. Because it was defined by path induction, this product operation satisfies \( e \cdot g \equiv g \).

For any elements \( g, g_1, g_2, g_3 : a \mapsto a \), we consider the following four equations:

1. the right unit law: \( g \mapsto g \cdot e \),
2. the left unit law: \( g \mapsto e \cdot g \),
3. the associativity law: \( g_1 \cdot (g_2 \cdot g_3) \mapsto (g_1 \cdot g_2) \cdot g_3 \),
4. the law of inverses: \( g \cdot g^{-1} \mapsto e \).

In Exercise 2.5.3, the reader has constructed explicit elements of these equations. If \( a \mapsto a \) were a set, then the equations above would all be propositions, and then, in line with the convention adopted in Section 2.15, we could simply say that Exercise 2.5.3 establishes that the equations hold. That motivates the following definition, in which we introduce a new set \( S \) to play the role of \( a \mapsto a \). We introduce a new element \( e : S \) to play the role of \( \text{refl}_a \), a new multiplication operation, and a new inverse operation. The original type \( A \) and its element \( a \) play no further role.

Definition 4.3.1. An abstract group consists of the following data.

1. A type \( S \).

Moreover, the type \( S \) should be a set. It is called the underlying set.

2. An element \( e : S \), called the unit or the neutral element.

3. A function \( S \rightarrow S \rightarrow S \), called multiplication, taking two elements \( g_1, g_2 : S \) to their product, denoted by \( g_1 \cdot g_2 : S \).

Moreover, the following equations should hold, for all \( g, g_1, g_2, g_3 : S \).

(a) \( g \cdot e = g \) and \( e \cdot g = g \) (the unit laws)
(b) \( g_1 \cdot (g_2 \cdot g_3) = (g_1 \cdot g_2) \cdot g_3 \) (the associativity law)

4. A function \( S \rightarrow S \), the inverse operation, taking an element \( g : S \) to its inverse \( g^{-1} \).

Moreover, the following equation should hold, for all \( g : S \).

(c) \( g \cdot g^{-1} = e \) (the law of inverses)
Remark 4.3.2. Strictly speaking, the proofs of the various equations are part of the data defining an abstract group, too. But, since the equations are propositions, the proofs are unique, and by the convention introduced in Remark 2.20.8, we can afford to omit them, when no confusion can occur. Moreover, one need not worry whether one gets a different group if the equations are given different proofs, because proofs of propositions are unique.

Remark 4.3.3. A monoid is a collection of data consisting only of (1), (2), and (3) from the list in Definition 4.3.1. In other words, the existence of inverses is not assumed. For this reason, the property that \( S \) is a set, the unit laws, and the associativity law are, together, known as the monoid laws.

Taking into account the introductory comments we have made above, we may state the following lemma.

Lemma 4.3.4. If \( G \) is a group, then \( UG \), together with \( e \colon \equiv \text{refl}_{\text{shc}} \), \( g^{-1} \colon \equiv \text{symm}_{\text{shc}}, g \) and \( h \colon g \cdot \equiv \text{trans}_{\text{shc}, \text{shc}}(g)(h) \), define an abstract group. We will let \( \text{abs}(G) \) denote that abstract group.

Proof. The type \( UG \) is a set, because \( BG \) is a groupoid. Exercise 2.5.3 shows that all the relevant equations hold, as required. \( \square \)

Definition 4.3.5. Given a group \( G \), the abstract group of Lemma 4.3.4, \( \text{abs}(G) \), is called the abstract group associated to \( G \).

Remark 4.3.6. Instead of including the inverse operation as part (4) of the structure (including with the property (4) (c)), some authors assume the existence of inverses by positing the following property.

\[ (5) \text{ for all } g : S \text{ there exists an element } h : S \text{ such that } e = g \cdot h. \]

We will now compare (5) to (4). Property (5) contains the phrase "there exists", and thus its translation into type theory uses the quantifier \( \exists \), as defined in Section 2.16. Under this translation, property (5) does not immediately allow us to speak of "the inverse of \( g \)". However, the following lemma shows that we can define an inverse operation as in (4) from a witness of (5) – its proof goes by using the properties (3) (a) and (3) (b) to prove that inverses are unique. As a consequence, we can speak "the inverse of \( g \)".

Lemma 4.3.7. Given a set \( S \) together with \( e \) and \( \cdot \) as in Definition 4.3.1 satisfying the unit laws, the associativity law, and property (5), there is an "inverse" function \( S \to S \) having property (4) (c) of Definition 4.3.1.

Proof. Consider the function \( \mu : S \to (S \to S) \) defined as \( g \mapsto (h \mapsto g \cdot h) \). Let \( g : S \). We claim that the fiber \( \mu(g)^{-1}(e) \) is contractible. Contractibility is a proposition, hence to prove it from (5), one can as well assume the actual existence of \( h \) such that \( g \cdot h = e \). Then \( (h, !) \) is an element of the fiber \( \mu(g)^{-1}(e) \). We will now prove that it is a center of contraction. For any other element \( (h', !) \), we want to prove \( (h, !) = (h', !) \), which is equivalent to the equation \( h = h' \). In order to prove the latter, we show that \( h \) is also an inverse on the left of \( g \), meaning that \( h \cdot g = e \). This equation is also a proposition, so we can assume from (5) that we have...
an element \( k : S \) such that \( h \cdot k = e \). Multiplying that equation by \( g \) on the left, one obtains
\[
k = e \cdot k = (g \cdot h) \cdot k = g \cdot (h \cdot k) = g \cdot e = g,\
\]
from which we see that \( h \cdot g = e \). Now it follows that
\[
h = h \cdot e = h \cdot (g \cdot h') = (h \cdot g) \cdot h' = e \cdot h' = h',
\]
as required. Hence \( \mu(g)^{-1}(e) \) is contractible, and we may define \( g^{-1} \) to
be the center of the contraction, for any \( g : S \). The function \( g \mapsto g^{-1} \)
satisfies the law of inverses (4) (c), as required.
\[ \square \]

Note that the proof above also shows the other law of inverses: for all \( g : S \) we have \( g^{-1} \cdot g = e \).

**Remark 4.3.8.** We may encode the type of abstract groups as follows. We let \( S \) denote the underlying set, \( e : S \) denote the unit, \( \mu : S \to S \to S \) denote the multiplication operation \( g \mapsto h \mapsto g \cdot h \), and \( i : S \to S \) denote the inverse operation \( g \mapsto g^{-1} \). Using that notation, we introduce names for the relevant propositions.

\[
\begin{align*}
\text{UnitLaws}(S, e, \mu) & \equiv \prod_{g : S} (\mu(g)(e) = g) \times (\mu(e)(g) = g) \\
\text{AssocLaw}(S, \mu) & \equiv \prod_{g, g_1, g_2 : S} \mu(g_1)(\mu(g_2)(g_3)) = \mu(\mu(g_1)(g_2))(g_3) \\
\text{MonoidLaws}(S, e, \mu) & \equiv \text{isSet}(S) \times \text{UnitLaws}(S, e, \mu) \times \text{AssocLaw}(S, \mu) \\
\text{InverseLaw}(S, e, \mu, i) & \equiv \prod_{g : S} (\mu(g)(i(g)) = e) \\
\text{GroupLaws}(S, e, \mu, i) & \equiv \text{MonoidLaws}(S, e, \mu) \times \text{InverseLaw}(S, e, \mu, i)
\end{align*}
\]

Now we define the type of abstract groups in terms of those propositions.

\[
\text{Group}^{\text{abs}} \equiv \sum_{S : \text{Set}} \sum_{e : S} \sum_{\mu : S \to S \to S} \sum_{i : S \to S} \text{GroupLaws}(S, e, \mu, i)
\]

Thus, following the convention introduced in Remark 2.8.2, an abstract
group \( G \) will be a quintuple of the form \( G \equiv (S, e, \mu, i, !) \). For brevity,
we will usually omit the proof of the properties from the display, since
it’s unique, and write an abstract group as though it were a quadruple
\( G \equiv (S, e, \mu, i) \).

**Remark 4.3.9.** That the concept of an abstract group synthesizes the idea
of symmetries will be justified in Section 4.9 where we prove that the
function \( \text{abs} : \text{Group} \to \text{Group}^{\text{abs}} \), whose definition can be inferred from the
proof of Lemma 4.3.4, is an equivalence.

**Remark 4.3.10.** If \( G \equiv (S, e, \mu, i) \) and \( G' \equiv (S', e', \mu', i') \) are abstract groups,
an element of the identity type \( G \to G' \) consists of quite a lot of information,
provided we interpret it by repeated application of Lemma 2.10.3.
First and foremost, we need an identification \( p : S \to S' \) of sets, but from
there on the information is a proof of a conjunction of propositions.\footnote{This is more interesting for oo-groups: in fact, we don’t know how
to define the type of “abstract oo-groups” in a way similar to Definition
4.3.1; such a definition would require infinitely many levels of operations
producing identifications of instances of operations of lower levels. And an identification would
similarly require infinitely many operations identifying the operations at all levels.}
An analysis shows that this conjunction can be shortened to the equations
\( e' = p(e) \) and \( \mu'(p(s), p(t)) = p(\mu(s, t)) \). A convenient way of obtaining
an identity \( p \) that preserves these equations is to apply univalence to an
equivalence \( f : S \to S' \) that preserves them. We call such a function an
isomorphism of abstract groups.\footnote{This is more interesting for oo-groups: in fact, we don’t know how
to define the type of “abstract oo-groups” in a way similar to Definition
4.3.1; such a definition would require infinitely many levels of operations
producing identifications of instances of operations of lower levels. And an identification would
similarly require infinitely many operations identifying the operations at all levels.}
Exercise 4.3.11. Perform the mentioned analysis.

Exercise 4.3.12. Let $G \equiv (S, e, \mu, i)$ be an abstract group. Define another structure $G^{op} \equiv (S, e, \mu^{op}, i)$, where $\mu^{op} : S \rightarrow S \rightarrow S$ sends $a, b : S$ to $\mu(b, a)$, i.e., $\mu^{op}$ swaps the order of the arguments as compared to $\mu$.

Show that $1 : S \rightarrow S$ defines an isomorphism $G \cong G^{op}$.

Exercise 4.3.13. Let $G \equiv (S, e, \mu, i)$ be an abstract group and let $g : S$. If $s : S$, let $\text{conj}^g(s) \equiv g \cdot s \cdot g^{-1}$. Show that the resulting function $\text{conj}^g : S \rightarrow S$ preserves the group structure (for instance $g \cdot (s \cdot s') \cdot g^{-1} = (g \cdot s \cdot g^{-1}) \cdot (g \cdot s' \cdot g^{-1})$) and is an equivalence. The resulting identification $\text{conj}^g : G \rightarrow G$ is called conjugation by $g$.

Remark 4.3.14. Without the demand that the underlying type of an abstract group or monoid is a set, life would be more complicated. For instance, for the case when $g$ is $e$, the unit laws $(3)$ $(a)$ of Definition 4.3.1 would provide two (potentially different) identifications $e \cdot e \rightarrow e$, and we would have to separately assume that they agree. This problem vanishes in the setup we adopt below for $\infty$-groups.

Exercise 4.3.15. For an element $g$ in an abstract group, prove that $e = g^{-1} \cdot g$ and $g = (g^{-1})^{-1}$. In other words (for the machines among us), given an abstract group $(S, e, \mu, i)$, give an element in the proposition
\[
\prod_{g : S} (e = \mu(i(g))(g)) \times (g = i(i(g))).
\]

Exercise 4.3.16. Prove that the types of monoids and abstract groups are groupoids.

Exercise 4.3.17. There is a leaner way of characterizing what an abstract group is: define a sheargroup to be a set $S$ together with an element $e : S$, a function $\ast : S \rightarrow S \rightarrow S$, sending $a, b : S$ to $a \ast b : S$, and the following propositions, where we use the shorthand $\overline{a} \equiv a \ast e$:

1. $e \ast a = a$,
2. $a \ast a = e$, and
3. $c \ast (b \ast a) = (c \ast b) \ast a$,

for all $a, b, c : S$. Construct an equivalence from the type of abstract groups to the type of sheargroups.

Exercise 4.3.18. Another and even leaner way to define abstract groups, highlighting how we can do away with both the inverse and the unit: a Furstenberg group is a nonempty set $S$ together with a function $\circ : S \rightarrow S \rightarrow S$, sending $a, b : S$ to $a \circ b : S$, with the property that

1. for all $a, b, c : S$ we have that $(a \circ c) \circ (b \circ c) = a \circ b$, and
2. for all $a, c : S$ there is a $b : S$ such that $a \circ b = c$.

Construct an equivalence from the type of Furstenberg groups to the type of abstract groups.

4.4 Homomorphisms

Remark 4.4.1. Let $G$ and $H$ be groups, and suppose we have a pointed function $k : BG \rightarrow BH$. Suppose also, for simplicity (and without

14Hint: in down-to-earth terms this boils down to the equation $(a \cdot b)^{-1} = b^{-1} \cdot a^{-1}$.

15Hint: setting $a \cdot b \equiv b \cdot a$ gives you an abstract group from a sheargroup and conversely, letting $a \cdot b \equiv b \cdot a^{-1}$ takes you back. On your way you may need at some point to show that $\overline{a} = a$; setting $c = \overline{a}$ and $b = a$ in the third formula will do the trick (after you have established that $\overline{a} = a$). This exercise may be good to look back to in the many instances where the inverse inserted when “multiplying from the right by $a$” is forced by transport considerations.

16Named after Hillel (Harry) Furstenberg who at the age of 20 published a paper doing this exercise.

18Hint: show that the function $a \mapsto a \circ a$ is constant, with value, say, $e$. Then show that $S$ together with the “unit” $e$, “multiplication” $a \cdot b \equiv a \circ (e \circ b)$ and “inverse” $b^{-1} \equiv e \circ b$ is an abstract group.
loss of generality), that \(\text{pt}_{BH} \equiv k(\text{pt}_{BG})\) and \(k_{pt} \equiv \text{refl}_{\text{pt}_{BH}}\). Applying Definition 2.6.1 yields a function \(f \equiv \text{ap}_k : \text{UG} \to UH\), which satisfies the following identities:

\[
\begin{align*}
  f(\text{refl}_{\text{pt}_{BG}}) &= \text{refl}_{\text{pt}_{BH}}, \\
  f(g^{-1}) &= (f(g))^{-1} \quad \text{for any } g : \text{UG}, \\
  f(g' \cdot g) &= f(g') \cdot f(g) \quad \text{for any } g, g' : \text{UG}.
\end{align*}
\]

The first one is true by definition, the others follow from Construction 2.6.2. These three identities assert that the function \(\text{ap}_k\) preserves, in a certain sense, the operations provided by Lemma 4.3.4 that make up the abstract groups \(\text{abs}(G)\) and \(\text{abs}(H)\). In the traditional study of abstract groups, these three identities play an important role and entitle one to call the function \(f\) a homomorphism of abstract groups.

A slight generalization of the discussion above will be to suppose that we have a general pointed map with an arbitrary pointing path \(k_{pt} : \text{pt}_{BH} \to k(\text{pt}_{BG})\), not necessarily given by reflexivity. Indeed, that works out, thereby motivating the following definition.

**Definition 4.4.2.** The type of group homomorphisms from \(G : \text{Group}\) to \(H : \text{Group}\) is defined to be

\[
\text{Hom}(G, H) \equiv \text{Copy}_\Omega(BG \to BH),
\]

i.e., it is a wrapped copy of the type of pointed maps of classifying spaces with constructor \(\Omega : (BG \to BH) \to \text{Hom}(G, H)\). We again write \(B : \text{Hom}(G, H) \to (BG \to BH)\) for the destructor, and we call \(Bf\) the classifying map of the homomorphism \(f\).

We would like to understand explicitly the effect of a general homomorphism \(f\) from \(G\) to \(H\) on the underlying symmetries \(\text{UG}, \text{UH}\), again without assuming that pointing path of \(Bf\) is given by reflexivity. So we should first study how pointed maps affect loops:

**Definition 4.4.3.** Given pointed types \(X\) and \(Y\) and a pointed function \(k : X \to Y\) (as defined in Definition 2.21.1), we define a function \(\Omega k : \Omega X \to \Omega Y\) by setting\(^{19}\)

\[
\Omega k(p) \equiv k_{pt}^{-1} \cdot \text{ap}_k(p) \cdot k_{pt}.
\]

**Remark 4.4.4.** If \(k : X \to Y\) has the reflexivity path \(\text{refl}_{\text{pt}_X}\) as its pointing path, then we have an identification \(\Omega k \equiv \text{ap}_k\). \(\rule{1cm}{.1mm}\)

**Definition 4.4.5.** Given groups \(G\) and \(H\) and a homomorphism \(f\) from \(G\) to \(H\), we define a function \(Uf : \text{UG} \to \text{UH}\) by setting \(Uf \equiv \Omega Bf\). In other words, the homomorphism \(\Omega Bf\) induces \(Uf\) as the map on underlying symmetries.

**Lemma 4.4.6.** Given groups \(G\) and \(H\) and a homomorphism \(f : \text{Hom}(G, H)\), the function \(Uf : \text{UG} \to \text{UH}\) defined above satisfies the following identities:

\[
\begin{align*}
  (Uf)(\text{refl}_{\text{pt}_{BG}}) &= \text{refl}_{\text{pt}_{BH}}, \\
  (Uf)(g^{-1}) &= ((Uf)(g))^{-1} \quad \text{for any } g : \text{UG}, \\
  (Uf)(g' \cdot g) &= (Uf)(g') \cdot (Uf)(g) \quad \text{for any } g, g' : \text{UG}.
\end{align*}
\]

\(^{19}\)Recall Definition 2.6.1 for \(\text{ap}\). Note also that \(\Omega k\) is pointed: we can identify \(\Omega k(\text{refl}_{\text{pt}_X})\) with \(\text{refl}_{\text{pt}_Y}\).
Proof. We write $f \equiv (f, \ell)$, where $p : pt_{BH} \to f.(pt_{BG})$. By induction on $p$, we reduce to the case where $pt_{BH} \equiv f.(pt_{BG})$. We finish by applying Remark 4.4.1.

**Definition 4.4.7.** A homomorphism $f : G \to H$ is an isomorphism if its classifying map $Bf$ is an equivalence. We let $\text{Iso}(G, H)$ be the subset of isomorphisms in $\text{Hom}(G, H)$. □

**Definition 4.4.8.** If $G$ is a group, then we use Definition 2.21.2 to define the identity homomorphism $\text{id}_G : G \to G$ by setting $\text{id}_G : \equiv \Omega(\text{id}_{BG})$. It is an isomorphism.

**Remark 4.4.9.** From Exercise 2.21.7, we have an equivalence

$$ (G \xrightarrow{\sim} \text{Group} H) \xrightarrow{\sim} \text{Iso}(G, H) $$

between the identity type between the groups $G$ and $H$ and the set of isomorphisms. We use the convention introduced in Remark 3.4.1 also here. That is, we allow ourselves to also write $p : \text{Iso}(G, H)$ for the isomorphism corresponding to an identification $p : G \xrightarrow{\sim} H$, and $Bp : BG \cong BH$ for the corresponding pointed equivalence of classifying types. Conversely, given an isomorphism $f : \text{Iso}(G, H)$, we may denote the corresponding path also as $f : G \xrightarrow{\sim} H$. □

**Definition 4.4.10.** If $G$, $G'$, and $G''$ are groups, and $f : G \to G'$ and $f' : G' \to G''$ are homomorphisms, then we use the definition of composition of pointed functions in Definition 2.21.1 to define the composite homomorphism $f' \circ f : G \to G''$ by setting $f' \circ f : \equiv \Omega(Bf' \circ Bf)$. □

Recall from Section 2.21, that when there is little danger of confusion, we may drop the subscript "." when talking about the unpointed structure.

**Remark 4.4.11.** To construct a function $\phi : \prod f : \text{Hom}(G, H) T(f)$, where $T(f)$ is a family of types parametrized by $f : \text{Hom}(G, H)$, it suffices to consider the case $f \equiv \Omega Bf$.\textsuperscript{20}

Identifications of homomorphisms $f \xrightarrow{\sim} \text{Hom}(G, H) f'$ are equivalent to identifications of pointed maps $Bf \xrightarrow{\sim} BH Bf'$; the latter are (by Lemma 2.10.3 and the fact that $BH$ is a groupoid) given by identifications of (unpointed) maps $h : Bf \xrightarrow{\sim} Bf'$ such that

$$ h.(sh_{BG})Bf_{pt} = Bf'_{pt}. $$

We will later show that if $G$ and $H$ are groups, then $\text{Hom}(G, H)$ is equivalent to the set of "abstract group homomorphisms" from $\text{abs}(G)$ to $\text{abs}(H)$ (see Lemma 4.10.1 below), but it is instructive to give a direct proof of the following.

**Lemma 4.4.12.** The type of homomorphisms $\text{Hom}(G, H)$ is a set for all groups $G, H$.

Proof. Given homomorphisms $f, f' : \text{Hom}(G, H)$, we use the equivalence just described,

$$ (f \xrightarrow{\sim} f') \xrightarrow{\sim} \sum_{h : Bf \xrightarrow{\sim} Bf'} h.(sh_{BG})Bf_{pt} = Bf'_{pt}, $$

so our goal is to prove that any two elements $(h, !), (j, !)$ of the right-hand side can be identified. By function extensional ty, the type $h \xrightarrow{\sim} j$ is...
equivalent to the proposition \( \prod_{\Gamma : BG} h(t) = j(t) \). So now we can use connectedness of \( BG \), and only check the equality on the point \( sh_G \). By assumption,

\[
h(sh_G) = Bf'pt Bf^{-1}pt = j(sh_G).
\]

This concludes the proof that \( f = f' \) is a proposition, or in other words that \( \text{Hom}(G, H) \) is a set. \( \square \)

**Example 4.4.13.**

1. Consider two sets \( S \) and \( T \). Recall from Example 4.2.18 that \( \Sigma_{Fin(S)} \cong \Sigma_S \rightarrow X \) is the component of the groupoid \( S \) containing \( S \), and when pointed at \( S \) represents the permutation group \( \Sigma_S \). The map \( \Sigma_{\Pi T} : \Sigma_{Fin(S)} \rightarrow \Sigma_{\Pi T} \) sending \( X \) to \( X \Pi T \) induces a group homomorphism \( \Sigma_S \rightarrow \Sigma_{\Pi T} \), pointed by the path \( \text{refl}_{\Pi T} : S \Pi T \rightarrow (\_ \Pi T)(S) \). Thought of as symmetries, this says that if you have a symmetry of \( S \), then we get a symmetry of \( S \Pi T \) (which doesn’t do anything to the second component of pairs in \( S \times T \)).

Likewise, we have a map \( \_ \times T : \Sigma_{Fin(S)} \rightarrow \Sigma_{\Pi T} \) sending \( X \) to \( X \times T \), inducing a group homomorphism \( \Sigma_S \rightarrow \Sigma_{\Pi T} \), pointed by the path \( \text{refl}_{\Pi T} : S \times T \rightarrow (\_ \times T)(S) \). Thought of as symmetries, this says that if you have a symmetry of \( S \), then we get a symmetry of \( S \times T \) (which doesn’t do anything to the second component of pairs in \( S \times T \)).

In particular, we get homomorphisms of symmetric groups \( \Sigma_m \rightarrow \Sigma_{m+n} \) and \( \Sigma_m \rightarrow \Sigma_{m+n} \), induced by identifications \( \text{Fin}(m + n) \rightarrow \text{Fin}(m) \Pi \text{Fin}(n) \) and \( \text{Fin}(m) \times \text{Fin}(n) \rightarrow \text{Fin}(m) \times \text{Fin}(n) \).

2. Let \( G \) be a group. Since there is a unique map from \( BG \) to \( 1 \) (uniquely pointed by the reflexivity path of the unique element of \( 1 \)), we get a unique homomorphism from \( G \) to the trivial group. Likewise, there is a unique morphism from the trivial group to \( G \), sending the unique element of \( 1 \) to \( \text{sh}_G \), and pointed by \( \text{refl}_{\text{sh}_G} \); the uniqueness follows from Lemma 2.9.10, cf. Lemma 3.3.11.

3. If \( G \) and \( H \) are groups, the projections \( BG \leftarrow BG \times BH \rightarrow BH \) and inclusions \( BG \rightarrow BG \times BH \leftarrow BH \) (e.g., the inclusion \( BG \rightarrow BG \times BH \) is given by \( z \mapsto (z, \text{sh}_H) \)) give rise to group homomorphisms between \( G \times H \) and \( G \) and \( H \), namely projections \( G \leftarrow G \times H \rightarrow H \) and inclusions \( G \rightarrow G \times H \leftarrow H \).

4. In Example 4.2.21 we gave an example of an isomorphism, namely one from the cyclic group \( C_m \) to \( \mathbb{Z}/m\mathbb{Z} \), and in Example 4.2.22 we looked at \( R_m : BZ \rightarrow B\Sigma_m \), which induces a homomorphism \( \_/m : \mathbb{Z} \rightarrow \Sigma_m \) factoring through \( \mathbb{Z}/m\mathbb{Z} \) (and \( C_m \)).

**Remark 4.4.14.** In the examples above, we insisted on writing the path pointing a group homomorphism, even when that path was a reflexivity path. We now adopt the convention that there is no need to specify the path in this case. Thus, given a map \( f : A \rightarrow B \) between connected groupoids and \( a : A \), the group homomorphism \( \text{Aut}_a(a) \rightarrow \text{Aut}_b(f(a)) \) defined by \( (f, \text{refl}_{f(a)}) \) will simply be referred to as \( f \).

However, it is important to understand that different homomorphisms can have the same underlying unpointed function. Consider, for example,

\[21\]The same argument shows that the type \( X \rightarrow Y \) is a set whenever \( X \) is connected and \( Y \) is a groupoid. A more general fact is that \( X \rightarrow Y \) is an \( n \)-type whenever \( X \) is \((k - 1)\)-connected and \( Y \) is \((n + k)\)-truncated, for all \( k \geq 0 \) and \( n \geq -1 \).

\[22\]The last identification is somewhat arbitrary, but let’s say it’s defined using the lexicographic ordering on the product.

\[23\]Since the classifying type \( B\Sigma_m \) is the 0-image of the classifying map of \( \_/m \), we’ll later say that \( C_m \) is the image of the homomorphism \( \_/m \), cf. Section 5.3.
the group $\Sigma_3$, whose classifying space is $B\Sigma_3 \equiv (\text{FinSet}_3, 3)$, and the
symmetry $\tau : U\Sigma_3$ that is defined (through univalence) by

$$0 \mapsto 1, \quad 1 \mapsto 0, \quad 2 \mapsto 2,$$

i.e., $\tau$ is the transposition $(0\, 1)$. Then the function $\text{id} : \text{FinSet}_3 \to \text{FinSet}_3$ gives rise to two elements of
$\text{Hom}(\Sigma_3, \Sigma_3)$: the first one is $(\text{id}, \text{refl}_3)$, which is simply denoted $\text{id}_{\Sigma_3}$; the second one is $(\text{id}, \tau)$, which we will denote $\tilde{\tau}$ temporarily. Let us prove $\text{id}_{\Sigma_3} \neq \tilde{\tau}$, that is, we suppose $\text{id}_{\Sigma_3} = \tilde{\tau}$ and derive a contradiction. By Definition 4.4.3 we get $\sigma = \tau^{-1} \sigma \tau$ for all $\sigma : U\Sigma_3$, so $\tau$ commutes with every other element of $U\Sigma_3$. This fails for the transposition $\sigma \equiv (1\, 2)$, since $\sigma(0) = 2$ while $\tau \sigma(0) = 1$. (See also Exercise 4.2.27.)

**Construction 4.4.15.** For pointed types $X, Y, Z$ and pointed maps $f : X \to Y$ and $g : Y \to Z$, we get an identification of type

$$\Omega(g \circ f) \equiv_{(\Omega X \to \Omega Z)} \Omega(g) \circ \Omega(f).$$

**Implementation of Construction 4.4.15.** Let $x$ denote the base point of $X$. By induction on $f_{pt}$ and on $g_{pt}$, we reduce to the case where $f_{pt} \equiv \text{refl}_{f(x)}$ and $g_{pt} \equiv \text{refl}_{g(f(x))}$, and it suffices to identify $\text{ap}_{g_{pt}}$ with $\text{ap}_{g}(\text{ap}_{f}(p))$. By Principle 2.9.17, it suffices to identify $\text{ap}_{g_{pt}}(p)$ with $\text{ap}_{g}(\text{ap}_{f}(p))$ for each $p : \Omega X$. For that purpose, it suffices to even identify $\text{ap}_{g_{pt}}(p)$ with $\text{ap}_{g}(\text{ap}_{f}(p))$ for any $x' : X$ and any $p : x \to x'$. Then by induction on $p$, it suffices to give an identification $\text{ap}_{g_{pt}}(\text{refl}_{x}) \sim \text{ap}_{g}(\text{ap}_{f}(\text{refl}_{x}))$, and that can be done by reflexivity, by observing that both sides are equal, by definition, to $\text{refl}_{f(x)}$.

**Corollary 4.4.16.** For composable group homomorphisms $\varphi : \text{Hom}(G, H)$, $\psi : \text{Hom}(H, K)$, we get an identification $U(\psi \circ \varphi) = U\psi \circ U\varphi$.

The following example expresses that $Z$ is a “free group with one generator”.

**Example 4.4.17.** Chapter 3 was all about the circle $S^1$ and its role as a “universal symmetry” and how it related to the integers. In our current language, $Z \equiv \Omega(S^1, \langle \cdot \rangle)$ and large parts of the universality is found in the following observation. If $G$ is a group, then the evaluation equivalence $\text{ev}_{BG} : (S^1 \to BG) \sim \Sigma_Y : BG, (y = y)$ of Theorem 3.1.2 yields an equivalence of sets

$$\text{ev}_{BG} : (S^1, \langle \cdot \rangle) \to BG \sim UG, \quad (f, f_{pt}) \mapsto f_{pt}^{-1} \text{ap}_{f}(\langle \rangle)_{f_{pt}}.$$  

The domain of this equivalence is equivalent to $\text{Hom}(Z, G)$. Hence, $\text{ev}_{BG}$ provides a way to identify $\text{Hom}(Z, G)$ with the underlying set $UG$. Like in Theorem 3.1.2, the inverse of $\text{ev}_{BG}$ is denoted $\text{ve}_{BG}$ and satisfies $\text{ve}_{BG}(g)(\langle \cdot \rangle) \equiv \text{sh}_G$ and $\text{ve}_{BG}(g)(\langle \rangle) = g$. Moreover, $\text{ve}_{BG}(g)$ is pointed by $\text{refl}_{\text{ve}_{BG}}$.

The following lemma states the “naturality” of $\text{ev}_{BG}$ in the previous example.

**Lemma 4.4.18.** Let $G$ and $H$ be groups and $f : \text{Hom}(G, H)$. Then the following diagram commutes,

$$\begin{array}{cc}
\text{Hom}(Z, G) & \xrightarrow{\text{ev}} & UG \\
\downarrow f_{\text{pt}} & & \downarrow Uf \\
\text{Hom}(Z, H) & \xrightarrow{\text{ev}} & UH,
\end{array}$$

where

$$\begin{array}{c}
\text{Hom}(Z, G) \xrightarrow{\text{ev}} UG \\
\downarrow f_{\text{pt}} \\
\text{Hom}(Z, H) \xrightarrow{\text{ev}} UH,
\end{array}$$

is the homomorphism from $\text{ev}_{BG}$.
where the horizontal maps evaluate the map on underlying symmetries at the loop \( \mathcal{U} : \mathcal{U} \).

**Proof.** Let \( k : \text{Hom}(\mathcal{Z}, G) \), giving \( \text{Uk} : \mathcal{U} \mathcal{Z} \rightarrow \mathcal{U} G \). Going across horizontally and then down, \( k \) is mapped first to \( \text{Uk}(\mathcal{U}) \), and then to \( \text{Uf}(\text{Uk}(\mathcal{U})) \).

Going the other way takes \( k \) to \( U(f \circ k)(\mathcal{U}) \), which is equal to \( \text{Uf}(\text{Uk}(\mathcal{U})) \) by Corollary 4.4.16. \( \square \)

**Exercise 4.4.19.** Let \( G \) be a group and \( A \) a groupoid. Use the definitions and Exercise 2.21.5 to construct equivalences between the types:

1. \( BG \rightarrow A \)
2. \( \sum_{a:A} \sum_{f:BG \rightarrow A} a \mapsto f(sh) \)
3. \( \sum_{a:A} (BG \rightarrow s(A, a)) \)
4. \( \sum_{a:A} \text{Hom}(G, \text{Aut}_A(a)) \)

The definition of group homomorphisms in Definition 4.4.2 should be contrasted with the usual – and somewhat more cumbersome – notion of a group homomorphism \( f : \mathcal{G} \rightarrow \mathcal{H} \) of abstract groups where we must ask of a function of the underlying sets that it in addition preserves the neutral element, multiplication, and inverse operation. In our setup this is simply true, as we saw in Lemma 4.4.6. In terms of the abstract groups determined by \( G \) and \( H \), we can write these equations as

\[
\begin{align*}
\text{Uf}(e_G) &= e_H \\
\text{Uf}(g \cdot g') &= \text{Uf}(g) \cdot \text{Uf}(g') & \text{for all } g, g' : \mathcal{U} G, \\
\text{Uf}(g^{-1}) &= (\text{Uf}(g))^{-1} & \text{for all } g : \mathcal{U} G.
\end{align*}
\]

Here we follow the usual custom of defining a homomorphism of abstract groups just in terms of the first two:

**Definition 4.4.20.** If \( \mathcal{G} \equiv (s, e_G, \cdot_G, \iota_G) \) and \( \mathcal{H} \equiv (t, e_H, \cdot_H, \iota_H) \) are two abstract groups, then the set of homomorphisms from \( \mathcal{G} \) to \( \mathcal{H} \) is

\[
\text{Hom}^{\text{abs}}(\mathcal{G}, \mathcal{H}) \equiv \sum_{f : S \rightarrow T} \left( e_H =_T f(e_G) \times \prod_{s, s' : S} f(s \cdot_G s') =_T f(s) \cdot_H f(s'). \right)
\]

If \( G \) and \( H \) are groups, the function

\[
\text{abs} : \text{Hom}(G, H) \rightarrow \text{Hom}^{\text{abs}}(\text{abs}(G), \text{abs}(H))
\]

is defined as the function \( f \mapsto \text{abs}(f) \equiv (\text{Uf}, !) \) made explicit in Definition 4.4.5 and satisfying the properties by Lemma 4.4.6. \( \square \)

**Exercise 4.4.21.** Note that the inverses play no rôle in the definition of a homomorphism of abstract groups. Prove that if \( (f, !) : \text{Hom}^{\text{abs}}(\mathcal{G}, \mathcal{H}) \), then the proposition \( f(g^{-1}) = (f(g))^{-1} \) holds for all \( g : \mathcal{G} \), so that we don’t have to require it separately. \( \square \)

**Remark 4.4.22.** Our definition of homomorphisms of abstract groups also makes sense for monoids as defined in Remark 4.3.3, and with our definition it is immediate that a homomorphism of abstract groups also defines a homomorphism of the underlying monoids. It is possible, however, to instead define the set of homomorphisms from \( \mathcal{G} \equiv (s, e_G, \cdot_G, \iota_G) \) to \( \mathcal{H} \equiv (T, e_H, \cdot_H, \iota_H) \) simply by

\[
\sum_{f : S \rightarrow T} \prod_{s, s' : S} f(s \cdot_G s') =_T f(s) \cdot_H f(s')
\]

Both \( e_H = f(e_G) \) and \( f(s \cdot_G s') =_T f(s) \cdot_H f(s') \) are propositions; hence a homomorphism of abstract groups is uniquely determined by its underlying function of sets, and unless there is danger of confusion we may write \( f \) instead of \((f, !)\).
Exercise 4.4.23. Prove this by deriving $e_H = f(e_G)$ from the above. 

Exercise 4.4.24. Prove that composition of the functions on the underlying sets gives a composition of homomorphisms of abstract groups.

Prove that if $f_0: \text{Hom}(G_0, G_1)$ and $f_1: \text{Hom}(G_1, G_2)$ then

$$\text{abs}(f_1 f_0) = \text{abs}(f_1) \text{abs}(f_0)$$

and that $\text{abs}(\text{id}_G) = \text{id}_{\text{abs}(G)}$. 

Example 4.4.25. Let $G = (S, e, \mu, i)$ be an abstract group and let $g: S$. In Exercise 4.3.13 we defined $\text{conj}: S \rightarrow S$ by setting $\text{conj}(s) = g \cdot s \cdot g^{-1}$ for $s : S$ and asked you to show that it “preserves the group structure”, i.e., represents a homomorphism

$$\approx \in \text{Hom}^{-1}(G, G)$$

called conjugation by $g$. Actually, we asked more: namely that conjugation by $g$ is an isomorphism, and hence determines an identification (for which we used the same symbol) $\text{conj}: G \approx G$.

If $H$ is some other abstract group, transport along $\text{conj}$ gives an identification $\text{conj}: \text{Hom}(H, G) \approx \text{Hom}(H, G)$ which should be viewed as “postcomposing with conjugation”. (Naturally, similar considerations go for elements in $H$, giving rise to “precomposition with conjugation”.)

Example 4.4.26. In terms of concrete groups one can think of conjugation as moving the shape of the concrete group along a path in the classifying type. This path can in particular be a loop at the shape. More precisely, let $G$ be the group, $y$ an element of $BG$, and $p$ a path of type $\text{sh} G \approx y$. Then $(p_0, p^{-1})$ is a pointed equivalence of type $BG \rightarrow_\equiv (BG, y)$ and hence induces an isomorphism from $G$ to $\Omega(BG, y)$. By Remark 4.4.9 we then get an identification of these groups. Moreover, by path induction on $p$, the equivalence $U(\Omega(p_0, p^{-1})) \equiv \Omega(p_0, p^{-1})$ of type $(\text{sh} G \rightarrow_\equiv \text{sh} G) \rightarrow_\equiv (y \rightarrow_\equiv y)^2$ can be identified with the map $g \mapsto p g p^{-1}$. In the special case of $y \equiv \text{sh} G$ this map is precisely $\text{conj}$ from Exercise 4.3.13. The more general form introduced here is also called conjugation. 

The above example motivates and justifies the following definition of a homomorphism from a group to its inner automorphisms, that is, automorphisms that come from conjugation. Such automorphisms will further be discussed in Section 5.7. Recall that $\text{BAut}(G)$ is the connected component of $G$ in the type Group, pointed at $G$.

Definition 4.4.27. Let $G$ be a group. Define the homomorphism $\text{inn}: G \rightarrow \text{Aut}(G)$ by setting

$$\text{Binn}: BG \rightarrow \text{BAut}(G), \quad y \mapsto \Omega(BG, y),$$

where the path pointing Binn is $p_{\text{inn}} \equiv \text{refl}_G: G \approx \text{Binn}(\text{sh} G)$. Note that $p_{\text{inn}}$ is well defined since $\text{Binn}(\text{sh} G) \equiv G$. Notice furthermore that the codomain of Binn is correct: since $BG$ is connected, the proposition $\|G \rightarrow \Omega(BG, y)||$ holds for all $y : BG$, by the argument in Example 4.4.26.

4.5 The sign homomorphism

In this section we’re going to define the very important sign homomorphism $\text{sgn}: \Sigma_n \rightarrow \Sigma_2$, defined for $n \geq 2$. To do this, we need to assign to every
n-element set $A$ a 2-element set $\text{Bsgn}(A)$.

We get this 2-element set as a quotient of the set of all possible ways of choosing elements from each 2-element subset of $A$, where two different such choices are deemed the same if they differ in an even number of pairs. Since choosing an element from a 2-element set is equivalent to ordering it (e.g., chosen element first), we can also talk about ways of ordering all possible 2-element subsets of $A$, or equivalently, ways of directing the complete graph on $A$. Figure 4.2 shows all 8 ways of directing the complete graph on a 3-element set divided into the 2 resulting equivalence classes.

To see that this really defines an equivalence relation, it helps to generalize a bit. Thus, fix a finite set $E$, and let $P : E \rightarrow B\Sigma_2$ be a family of 2-element sets parametrized by $E$.

**Definition 4.5.1.** The parity relation ~ on $\prod_{e \in E} P(e)$ relates functions that disagree in an even number of points. That is, $f \sim g$ holds if and only if the subset $\{ e \in E \mid f(e) \neq g(e) \}$ has an even number of elements.

**Lemma 4.5.2.** The parity relation ~ is an equivalence relation on the set $\prod_{e \in E} P(e)$, and the quotient is a 2-element set if $E$ is nonempty, otherwise it is a 1-element set.

Proof. The ~ relation is clearly symmetric, and it is reflexive, since the empty set has an even number of elements. To show transitivity, let $f_1, f_2, f_3 : \prod_{e \in E} P(e)$. We can partition $E$ according to whether the $f_i$ agree or disagree:

$$E_{ij} \equiv \{ e : E \mid f_i(e) = f_j(e) \}, \quad F_{ij} \equiv \{ e : E \mid f_i(e) \neq f_j(e) \}.$$ 

By transitivity of equality, $E_{ij} \cap E_{jk} \subseteq E_{ik}$, for all $i, j, k$. Hence, the Venn diagram of these sets has the simplified form shown in the margin, where we set

$$D \equiv \{ e : E \mid f_1(e) = f_2(e) = f_3(e) \}, \quad E_{ij}' \equiv E_{ij} \setminus D.$$

Here we also use that $E_{12} \cup E_{23} \cup E_{13} = E$ (as subsets of $E$), since of the three function values at any $e \in E$, two must agree.

We now find $F_{12} = E_{13}' \cup E_{23}'$ (disjoint union), and similarly for $F_{13}$ and $F_{23}$. Taking cardinalities, we get

$$\text{Card}(F_{12}) + \text{Card}(F_{13}) + \text{Card}(F_{23}) = 2(\text{Card}(E_{12}') + \text{Card}(E_{13}') + \text{Card}(E_{23}')),$$

so if two of the $F_{ij}'$’s have an even number of elements, then so does the third. We also see that at least one of the $F_{ij}'$’s has even cardinality, so the quotient has at most 2 elements.

Finally, if $E$ is empty, then $\prod_{e \in E} P(e)$ is contractible, so the quotient is contractible. Assume now that $E$ is nonempty. To show the proposition that the quotient is a 2-element set, we may assume that $E$ is the $n$-element set $\{1, \ldots, n\}$ (since $n > 0$), and (by induction on $n$) that each set $P(e)$ is $\{\pm1\}$ (our favorite 2-element set for the moment). Then any function is equivalent to either the all $+1$-function or the function that is $-1$ at 1 and $+1$ otherwise, according to how many times it takes the value $-1$. \qed

**Remark 4.5.3.** The groupoid $E \rightarrow B\Sigma_2$ is connected whenever $E$ is a finite set, and we can make it pointed by taking the constant map to $\text{sh}_\Sigma_2$.

![Figure 4.2: The two equivalence classes of directions of the complete graph on a 3-element set.](image)
as base point. We denote the corresponding group by $\Sigma^E_n \equiv \Omega(E \to B\Sigma_2, c_s/h_{\Sigma_2})$; it is an $E$-fold product of the group $\Sigma_2$. Our construction $P \mapsto (((\prod_{E} P(e))/\sim, \text{for } E \text{ nonempty}, defines a map } (E \to B\Sigma_2) \to B\Sigma_2$, which can be pointed by the identification indicated in the proof above, and thus defines a homomorphism $\mu_E : \text{Hom}(\Sigma^E_2, \Sigma_2)$. We also have this homomorphism when $E$ is empty, since then $B\Sigma^E_2$ is contractible, so $\Sigma^E_2$ is the trivial group.

Exercise 4.5.4. Show that the set of elements of $\Sigma^E_n$ can be identified with $\{\pm 1\}^E$, and under this identification, $U\mu_E$ maps a function $s : E \to \{\pm 1\}$ to the product of its values.28

Definition 4.5.5. A local ordering of a finite set $A$ is an element of the set $\prod_{E(A)} P(e)$, where $E(A)$ is the set of 2-element subsets of $A$, and $P : E(A) \to B\Sigma_2$ maps a 2-element subset to the underlying 2-element set.

A sign ordering of a finite set $A$ is an element of $(\prod_{E(A)} P(e))/\sim$, i.e., the quotient of the set of local orderings modulo the parity relation.29

Definition 4.5.6. The sign homomorphism $\text{sgn} : \text{Hom}(\Sigma_n, \Sigma_2)$ is defined via the pointed map $\text{Bsgn} : B\Sigma_n \to B\Sigma_2$, where $\text{Bsgn}(A) \equiv B\mu_{E(A)}(P)$. We make $\text{Bsgn}$ pointed using the total ordering on the standard $n$-element set, $\text{sh}_{\Sigma_n}$ to identify each 2-element subset with the standard 2-element set, and using the pointedness of $B\mu$.

Something interesting happens when we consider permutations on other shapes in $B\Sigma_n$, i.e., arbitrary $n$-element sets $A$. The same map, $\text{Bsgn}$, can be considered as a map $B\text{Aut}(A) \to B\Sigma_2$, but we cannot make this pointed uniformly in $A$.29 However, the self-identifications of a 2-element set $T$, $(T \to T)$, can be identified with $\{\pm 1\}$.30 according to whether it transposes the elements of the $T$, or not. Hence, we can define the sign of any permutation of a finite set:

Definition 4.5.7. Let $A$ be a finite set, and let $\sigma$ be a permutation of $A$. If the cardinality of $A$ is 0 or 1, then the sign of $\sigma$ is $+1$. Otherwise, the sign of $\sigma$ is $\pm 1$ according to whether $\text{Bsgn}_{(A)}$ swaps the elements of the 2-element set $\text{Bsgn}_{(A)}$, or not.

We write $\text{sgn}(\sigma) : \{\pm 1\}$ for the sign of $\sigma$.31

For permutations of the standard $n$-element set, this is the same as the value $\text{Usign}(\sigma) : \Upsilon \Sigma_2$. Note that $\text{sgn}$ defines an abstract homomorphism from $\text{Aut}(A)$ to $\Sigma_2$ for each $A$, since it does so for $A \equiv \text{sh}_{\Sigma_n}$. Hence we in fact have homomorphisms $\text{sgn}^A : \text{Hom}(\text{Aut}(A), \Sigma_2)$ for all finite sets $A$.31

Lemma 4.5.8. (1) The sign of a transposition is $-1$.

(2) The sign of a k-cycle is $(-1)^{k-1}$.

(3) The identity permutation can only be expressed as a product of an even number of transpositions.

Proof. For (1), it suffices to consider the transposition $(1 2)$ of the standard $n$-element set $\{1, 2, \ldots, n\}$. Relative to the standard local ordering $(1 < 2, 1 < 3, \ldots, n-1 < n)$, the transposition only changes the ordering $1 < 2$ to $2 < 1$, thus differing at exactly one place.

Now (2) follows via Exercise 3.7.4.

For (3), assume $\text{id}_A = (a_1 b_1) \cdots (a_k b_k)$, and take the sign of both sides. Since $\text{sgn}$ is a homomorphism, we get $+1 = (-1)^k$, so $k$ is even. □

28Note that this works even when $E$ is empty, since the product of an empty collection of numbers is $+1$.

29Why not? A construction $p : \prod A \to (\text{Bsgn}(A) \to \text{sh}_{\Sigma_2})$ would amount to an identification of $\text{Bsgn}$ with the constant map.

30In this section, we identify $\Upsilon \Sigma_2$ with the set $\{\pm 1\}$, which has a compatible abstract group structure given by multiplication.

31We need to add the decoration signifying which finite set $A$ is considered as reference, since the classifying map depends on it: We can take $\text{Bsgn}^A(B) \equiv (\text{Bsgn}(A) \to \text{Bsgn}(B))$ with the pointing given by the above identification of $\text{Bsgn}^A(A)$ with $\{\pm 1\}$.
Corollary 4.5.9. If a permutation $\sigma$ is expressed as a product of transpositions in two ways,

$$\sigma = (a_1 b_1) \cdots (a_m b_m) = (c_1 d_1) \cdots (c_n d_n),$$

then the parity of $m$ equals that of $n$, and we have $\text{sgn}(\sigma) = (-1)^m = (-1)^n$.

Exercise 4.5.10. Here’s a different way of finding the sign of a permutation of the standard $n$-element set $n$ (or of any totally ordered $n$-element set — but these are all uniquely identified with $n$).

For $\sigma : n \to n$, we call an ordered pair of elements $i, j$ with $i < j$ but $\sigma(i) > \sigma(j)$ an inversion. If we represent $\sigma$ graphically as in Fig. 4.3, then inversions are crossings of the edges $(i, \sigma(i))$ and $(j, \sigma(j))$. Show that $\text{sgn}(\sigma) = (-1)^{\text{inv}(\sigma)}$, where $\text{inv}(\sigma)$ is the number of inversions.

Remark 4.5.11. The two graphical representations Figs. 3.11 and 4.3 each have their uses: In the former, the cycle decomposition is immediately visible, while permutations are easily composed using the latter style. Note that the number of inversions depend on the linear ordering, whereas the sign itself does not.

We also remark that when we compose permutations in the latter style, we don’t immediately see the number of crossings/inversions, but we can imagine “pulling the strings taut”, whereby the parity of the number of crossings (and thus the sign) is preserved, as seen in Fig. 4.4.

4.6 $\infty$-groups

Disregarding the set-condition we get the simpler notion of $\infty$-groups:

Definition 4.6.1. The type of $\infty$-groups is

$$\infty \text{-Group} \equiv \text{Copy}(\mathbb{U}^{\geq 0}), \text{ where } \mathbb{U}^{\geq 0} \equiv \sum_{A : \mathbb{U}} \sum_{a : A} \text{isConn}(A)$$

is the type of pointed, connected types.

As for groups, we have the constructor $\Omega : \mathbb{U}^{\geq 0} \to \infty \text{-Group}$ and the destructor $B : \infty \text{-Group} \to \mathbb{U}^{\geq 0}$.

Remark 4.6.2. Just as “group” is a synonym for “pointed, connected groupoid” (wrapped with $\Omega$), “$\infty$-group” is a synonym for “pointed, connected type” (wrapped with $\Omega$). As for pointed, connected groupoids, we suppress the propositional information from the notation, and write $(A, a)$ instead of $(A, a, 1)$ for an pointed, connected type.

Definition 4.6.3. Given $G : \infty \text{-Group}$, the underlying pointed type $BG : \mathbb{U}$, is called the classifying type of $G$ and $\text{sh}_G : pt_{BG}$ is called the designated shape.

Definition 4.6.4. For any type $A$ with a specified point $a$, we define the automorphism $\infty$-group of $a : A$ by

$$\text{Aut}_A(a) \equiv \Omega(A_{(a)}, (a, 1)),$$

i.e., $\text{Aut}_A(a)$ is the $\infty$-group with classifying type $B\text{Aut}_A(a) \equiv (A_{(a)}, (a, 1))$, the connected component of $A$ containing $a$, pointed at $a$.

Remark 4.6.5. It can certainly happen that the connected component of $A$ containing $a$ is groupoid, even though $A$ itself is not a groupoid. For example, consider a type universe $\mathbb{U}$ and a set $S : \mathbb{U}$. Then $\mathbb{U}_{(S)}$ is
a groupoid, and the automorphism ∞-group $\text{Aut}_G(S)$ is an ordinary group.

Because we have an embedding $\mathcal{U}_G = 1 \xhookrightarrow{} \mathcal{U}_G^\infty$, we get a corresponding embedding $\text{Group} \xhookrightarrow{} \infty\text{Group}$. 

**Definition 4.6.6.** A homomorphism of ∞-groups is a pointed function of classifying types, i.e., given two ∞-groups $G$ and $H$, we define

$$\text{Hom}(G, H) \equiv \text{Copy}(BG \to BH).$$

Given $f \equiv \Omega Bf : \text{Hom}(G, H)$, we call $Bf : BG \to BH$ the classifying map of $f$. 

### 4.7 G-sets

One of the goals of Section 4.9 is to prove that the types of groups and abstract groups are equivalent. In doing that, we are invited to explore how abstract groups should be thought of as symmetries and introduce the notion of a $G$-set. However, this takes a pleasant detour where we have to explore the most important feature of groups: they act on things (giving rise to symmetries)! 

Before we handle the more complex case of abstract groups, let us see what this looks like for groups.

**Definition 4.7.1.** For $G$ a group, a $G$-set is a function

$$X : BG \to \text{Set},$$

and $X(\text{sh}_G)$ is referred to as the underlying set. If $p : x = y$ in $BG$, then the transport function $X(x) \to X(y)$ induced by $X(p) \equiv a_p X(p) : X(x) = X(y)$ is also denoted by $X(p)$. We denote $X(p)(a)$ by $p \cdot_X a$. The operation $\cdot_X$ is called the group action of $X$. When $X$ is clear from the context we may leave out the subscript $X$. In particular, if $g : UG$, then $X(g)$ is a permutation of the underlying set of $X$.

The type of $G$-sets is 

$$\text{G-Set} \equiv (BG \to \text{Set}).$$

If $x : BG$, then $X(x)$ is a “twisted” version of the underlying set.

**Remark 4.7.2.** The reader will notice that the type of $G$-sets is equivalent to the type of set bundles over $BG$. The reason we have allowed ourselves two names is that our focus is different: for a $G$-set $X : BG \to \text{Set}$ we focus on the sets $X(z)$, whereas when talking about set bundles the first projection $\sum_z : BG \times BG \to BG$ takes center stage. Each focus has its advantages.

**Example 4.7.3.** If $G$ is a group, then

$$\text{Pr}_G : BG \to \text{Set}, \quad \text{Pr}_G(z) \equiv P_{z G}(z) \equiv (\text{sh}_G = z)$$

is a $G$-set called the principal $G$-torsor. We’ve seen this family before in the guise of the (preimages of the) “universal set bundle” of Example 3.3.9!

There is nothing sacred about starting the equality $\text{sh}_G = z$ in $\text{sh}_G$. Let

$$P_z : BG \to \text{G-Set}$$

be the type of $G$-sets, then $P_z$ is called the principal $G$-torsor. We’ve seen this family before in the guise of the (preimages of the) “universal set bundle” of Example 3.3.9!

There is nothing sacred about starting the equality $\text{sh}_G = z$ in $\text{sh}_G$. Let

$$P_z : BG \to \text{G-Set}$$

be the type of $G$-sets, then $P_z$ is called the principal $G$-torsor. We’ve seen this family before in the guise of the (preimages of the) “universal set bundle” of Example 3.3.9! 

Much of what follows will work equally well for $\infty$-groups; if $G$ is an infinity group, a $G$-type is a function $X : BG \to \mathcal{U}$.

The term “$G$-torsor” will reappear several times and will mean nothing but a $G$-type in the component of $\text{Pr}_G$ – a “twisted” version of $\text{Pr}_G$. 

³Note that in this case $\cdot : (x = y) \to X(x) \to X(y)$. See Example 4.7.3 for a special case where $\cdot_X$ is indeed path composition.
denote the map sending \( y : BG \) to the G-set \( P_y \). Applying \( P \) to a path \( q : y = y' \) induces an equivalence from \( P_y \) to \( P_{y'} \) that sends \( p : y = z \) to \( pq^{-1} : y' = z \). As a matter of fact, Theorem 4.8.6 will identify \( BG \) with the type of G-torsors via the map \( P \), simply denoted as \( P \), using the full transport structure of the identity type \( P_y(z) \equiv (y = z) \).

**Example 4.7.4.** If \( G \) is a group (or \( \infty \)-group), then

\[
\text{Ad}_G : BG \to \mathcal{U}, \quad \text{Ad}_G(z) \equiv (z = z)
\]

is a G-set (or G-type) called the adjoint \( G \)-set (or G-type). Notice that by the induction principle for the circle,

\[
\sum_{z : BG} \text{Ad}_G(z) = \sum_{z : BG} (z = z)
\]

is equivalent to the type of (unpointed!) maps \( S^1 \to BG \), known in other contexts as the free loop space of \( BG \), an apt name given that it is the type of “all symmetries in \( BG \).” The first projection \( \sum_{z : BG} \text{Ad}_G(z) \to BG \) correspond to the function \( (S^1 \to BG) \to BG \) given by evaluating at \( \bullet \).

**Example 4.7.5.** Recall that a homomorphism \( f : \text{Hom}(H, G) \) consists of an unpointed map \( F : BH \to BG \), together with a \( p_f : \text{sh}G = F(\text{sh}H) \), so if, for \( x : BH \) and \( y : BG \), we define

\[
\text{Hom}(H, G)(x, y) \equiv \sum_{F : BH \to BG.} (y = F(x))
\]

we see that \( \text{Hom}(H, G) \) may be considered to be a \( H \times G \)-set

\[
\text{Hom}(H, G) : BH \times BG \to \text{Set}.
\]

We will be particularly interested in the restriction to \( G \), giving a G-set for which we recycle the notation:

\[
\text{Hom}(H, G)(y) \equiv \text{Hom}(H, G)(\text{sh}H, y) : \sum_{F : BH \to BG.} (y = F(\text{sh}H)).
\]

**Exercise 4.7.6.** Provide an identification between the G-sets \( \text{Ad}_G \) and \( \text{Hom}(\mathbb{Z}, G) \) of Example 4.7.4 and Example 4.7.5.

**Example 4.7.7.** If \( G \) is a group and \( X \) is a set, then

\[
\text{triv}_G(X)(z) \equiv X
\]

is a G-set. Examples of this sort (regardless of \( X \)) are called trivial G-sets.

**Remark 4.7.8.** A G-set \( X \) is often presented by focusing on the underlying set \( X(\text{sh}G) \) and providing it with a structure relating it to \( G \) determining the entire function \( X : BG \to \text{Set} \).

More precisely, since \( BG \) is connected, a G-set \( X : BG \to \text{Set} \) factors through the component \( \text{Set}(X(\text{sh}G)) \equiv \sum_{Y : \text{Set}} X(\text{sh}G) = Y \) which contains the point \( X(\text{sh}G) \). Since \( BG(\text{sh}G) \equiv (\text{Set}(X(\text{sh}G)), X(\text{sh}G)) \) the G-set \( X \) can, without loss of information, be considered as a homomorphism from \( G \) to the permutation group \( \Sigma X(\text{sh}G) \) of \( X(\text{sh}G) \), that is, a pointed map

\[
BG \to \Sigma X(\text{sh}G).
\]
Conversely, if $X$ is any set and we have a homomorphism from $G$ to $\Sigma_X$, i.e., a pointed map $(f, p) : BG \rightarrow \Sigma_X$, then the composite

$$BG \xrightarrow{(f)} \text{Set}_{(X)} \xrightarrow{\text{fst}} \text{Set}$$

is a $G$-set, and the value at $\text{sh}_G$ is identified with $X$.

The constructions in the previous two paragraphs yields the following equivalence:

$$\text{G-Set} \xrightarrow{\approx} \sum_{X : \text{Set}} BG \rightarrow \text{B}_\Sigma X.$$

**Exercise 4.7.9.** Show: if $X$ is a type family with parameter type $BG$ and $X(\text{sh}_C)$ is a set, then $X$ is a $G$-set.

**Exercise 4.7.10.** Prove that a group $G$ is abelian group if and only if the $G$-sets $\text{Ad}_G$ and $\text{triv}_G(\text{UG})$ are identical.

### Transitive $G$-sets

We end the section with some observations regarding so-called transitive $G$-sets which will be valuable when we move on to discussing subgroups. Classically, a $\text{abs}(G)$-set (a notion we have yet not defined) $X'$ is said to be transitive if there exists a $b : X'$ such that for all $a : X'$ there exists a $g : X'$ with $a = g \cdot b$. In our world this translates to

**Definition 4.7.11.** A $G$-set $X : BG \rightarrow \text{Set}$ is transitive if the proposition

$$\text{isTrans}(X) : \equiv \prod_{y : BG} \exists a \exists b : X(y) a : X(y) g : y = y$$

holds.

**Remark 4.7.12.** Note that the mention of $y$ is redundant in the definition: by connectedness (cf. Exercise 2.16.9) it is enough to demand

$$\exists a \in X(\text{sh}_C) \exists b : X(\text{sh}_C) \forall g : UG : a = g \cdot b.$$

In other words, $X$ is transitive if and only if there exists a $b : X(\text{sh}_C)$ such that the map $\dashv : UG \rightarrow X(\text{sh}_C)$ is surjective.

Yet another equivalent way of expressing that $X$ is transitive is to say that $X(\text{sh}_C)$ is nonempty and for any $a, b : X(\text{sh}_C)$ there exists some $g : UG$ with $a = g \cdot b$.

**Lemma 4.7.13.** A $G$-set is transitive if and only if the associated set bundle is connected.

**Proof.** Consider a $G$-set $X : BG \rightarrow \text{Set}$ and the associated set bundle $f : \tilde{X} \rightarrow BG$ where $\tilde{X} : = \sum_y : BG X(y)$ and $f$ is the first projection. Now, $\tilde{X}$ is connected if and only if there exists a $y : BG$ and a $b : X(y)$ such that for all $z : BG$ and $a : X(z)$ there exists a $g : y = z$ such that $a = g \cdot b$. Since $BG$ is connected, this is equivalent to asserting that there exists a $g : UG$ such that $a = g \cdot b$. \hfill $\Box$

Recall that for type families $X, X' : T \rightarrow U \text{L}$, and $f : \prod_{y : T} X(y) \rightarrow X'(y)$, we write $f_y : X(y) \rightarrow X'(y)$ (instead of the more correct $f(y)$) for its evaluation at $y : T$. We must be careful not to focus too much on the underlying set. For instance, even though the underlying set of both $\text{Ad}_G$ and $\text{Pr}_G$ is $\text{UG}$, in general $\text{Ad}_G$ and $\text{Pr}_G$ are very different $G$-sets. To drive this point home, compare the illustrations of transport along a $p : \text{UG}$ for the two:

$$\begin{array}{c}
\text{sh}_G \xrightarrow{p} \text{sh}_G \\
\downarrow q \downarrow \downarrow \text{Ad}_G(q, p) \\
\text{sh}_G \xrightarrow{\text{triv}_G(p, q)} \\
\downarrow \downarrow \downarrow \text{Pr}_G(p, q) \\
\text{sh}_G \xrightarrow{p} \text{sh}_G
\end{array}$$

A third $G$-set with underlying set $\text{UG}$ is $\text{triv}_G(\text{UG})$. A second way of expressing this is the following:
Lemma 4.7.14. Let \( X, X' : \text{BG} \to \text{Set} \) be \( G \)-sets. Let \( y : \text{BG} \) and \( b : X(y) \). Suppose that \( X \) is transitive. Then the evaluation map

\[
ev : (X = X') \to X'(y), \quad \ev(f) \equiv f_y(b)
\]
is injective.

Proof. In view of function extensionality, our claim is that the evaluation map \( \ev : \prod_{X : \text{BG}} (X(x) = X(x)) \to X(y) \) given by the same formula is injective; that is all \( f \)s with the same value \( f_y(b) \) are identical.

For \( a : X'(y) \), consider an \( f : X = X' \) with \( f_y(b) = a \). Let \( z : \text{BG} \) and \( c : X(z) \). For any \( g : y = z \) such that \( g \cdot b = c \) we have \( f_z(c) = f_z(g \cdot b) = g \cdot f_y(b) = g \cdot a \): the value does not depend on \( f \). Since we try to prove a proposition we are done. \( \square \)

4.7.15 Actions in a type

Oftentimes it is interesting not to have an action on a set, but on an element in any given type (not necessarily the type of sets). For instance, a group can act on another, giving rise to the notion of the semidirect product in Section 4.14. We will return these more general types of actions many times.

Definition 4.7.16. If \( G \) is any (possibly higher) group and \( A \) is any type of objects, then we define an action by \( G \) in \( A \) as a function

\[
X : \text{BG} \to A.
\]

The particular object of type \( A \) being acted on is \( X(\text{sh}_G) : A \), and the action itself is given by transport. This generalizes our earlier definition of \( G \)-sets, \( X : \text{BG} \to \text{Set} \).

Definition 4.7.17. The standard action of \( G \) on its designated shape \( \text{sh}_G \) is obtained by taking \( A \equiv \text{BG} \) and \( X \equiv \text{id}_B \).

Example 4.7.18. An action of \( G \) on its set \( U_G \) of symmetries is provided by taking \( X \) to be the principal torsor \( \text{Pr}_G \) as defined in Example 4.7.3.

Notice that the type \( \text{BG} \to A \) is equivalent to the type

\[
\sum_{a : A} \text{hom}(G, \text{Aut}_A(a)),
\]

that is, the type of pairs of an element \( a : A \), and a homomorphism from \( G \) to the automorphism group of \( A \). This equivalence maps an action \( X : \text{BG} \to A \) to the pair consisting of \( X(\text{sh}_G) \) and the homomorphism represented by the pointed map from \( \text{BG} \) to the pointed component \( A(a) \) given by \( X \).

Because of this equivalence, we define a \( G \)-action on \( a : A \) to be a homomorphism from \( G \) to \( \text{Aut}_A(a) \).

Many times we are particularly interested in actions on types, i.e., \( A \) is a universe:

\[
X : \text{BG} \to \mathcal{U}.
\]

In this case we can talk about fixed points and orbits as follows.

Definition 4.7.19. If \( X : G \to \mathcal{U} \), then orbit type of the action as \( X_{hG} \)\

\[
X_{hG} \equiv \sum_{z : \text{BG}} X(z),
\]

We use superscripts and subscripts many places and truncations of orbit types, and to distinguish the orbits and fixed points are decorated with “\( hG \)”, following a convention in homotopy theory.
This works equally well with $\infty$-groups: $G$-torsors are in that case $G$-types in the component of the principal torsor. There is no conflict with the case when the $\infty$-group $G$ is actually a group since then any $G$-type in the component of the principal $G$-torsor will be a $G$-set.

4.8 The classifying type is the type of torsors

This section can be seen as a motivation for the use of torsors. In Section 4.9 we'll use this concept to prove that the type of groups and the type of abstract groups are equivalent by classifying abstract groups in terms of their pointed connected groupoid of torsors. To see how this might work it is good to start with the case of a (concrete) group $G$. In the end we want the torsors of $\text{abs}(G)$ to be equivalent to $BG$, so to get the right definition we should first explore what the torsors of $G$ look like and prove Theorem 4.8.6 showing that $BG$ is equivalent to the type of $G$-torsors.

**Definition 4.8.1.** Given a group $G$, the type of $G$-torsors is

$$\text{Torsor}_G := \sum_{X : G\text{-Set}} ||\text{Pr}_G = X||,$$

where $\text{Pr}_G$ is the principal $G$-torsor of Example 4.7.3.

**Remark 4.8.2.** For $G$ a group, the type of $G$-torsors is just another name for the component of the type of set bundles of $BG$ containing the universal set bundle.

Observe that for a group $G$, $\text{Torsor}_G$ is a connected groupoid (admittedly in a higher universe) and so – by specifying the base point $\text{Pr}_G$ – it represents a group! Guess which one!

For $z : BG$, recall the definition of $P_z : BG \to \text{Set}$ as the $G$-set with $P_z(y) \equiv (z = y)$ (so that in particular $\text{Pr}_G \equiv P_{\text{sh}_G}$). Note that $P_z$ is a $G$-torsor.

**Definition 4.8.3.** Let

$$P : BG \to, (\text{Torsor}_G, \text{Pr}_G)$$

be the pointed map given by sending $z : BG$ to $P_z$ and by the identification $\text{refl}_{P_{\text{sh}_G}} : P_{\text{sh}_G} = \text{Pr}_G$.

If $G$ is not clear from the context, we may choose to write $P^G$ instead of $P$.

**Example 4.8.4.** For $y, z : BG$ we make the induced map

$$P : (y = z) \to (P_y = P_z),$$

and the type of fixed points as

$$X^{hG} \equiv \prod_{z : BG} X(z).$$

The set of orbits is the set-truncation of the orbit type,

$$X/G \equiv ||X^{hG}||_0.$$

We say that the action is transitive if $X/G$ is contractible. Notice that this notion of transitive coincides with the one we introduced in Definition 4.7.11: that $X/G$ is contractible exactly encodes that there is just one “orbit”: there is a $b : X(\text{sh}_G)$ so that for any $a : X(\text{sh}_G)$ there is a $g : UG$ such that $a = g \cdot b$. 

This works equally well with $\infty$-groups: $G$-torsors are in that case $G$-types in the component of the principal torsor. There is no conflict with the case when the $\infty$-group $G$ is actually a group since then any $G$-type in the component of the principal $G$-torsor will be a $G$-set.
or rather its composite with the equivalence to \( \prod_{x:BG} P_y(x) = P_z(x) \), explicit. For \( q : y = z \), the transport \( P_q : \prod_{x:BG} P_y(x) = P_z(x) \) is obtained by sending \( p : P_y(x) \equiv (y = x) \) to

\[
P_q(p) \equiv p q^{-1} : P_z(x) \equiv (z = x).
\]

**Lemma 4.8.5.** For \( y, z : BG \) the induced map (i.e., transport) of identity types

\[
P : (y = z) \to (P_y = P_z)
\]

is an equivalence.

**Proof.** We craft an inverse \( Q : (P_y = P_z) \to (y = z) \) for \( P \). Given an identity \( f : P_y = P_z \), the map \( f_y : (y = y) \to (z = y) \) maps the reflexivity path \( \text{refl}_y \) to a path \( f_y(\text{refl}_y) : z = y \), and we define

\[
Q(f) \equiv f_y(\text{refl}_y)^{-1}
\]

First, \( Q \) is an inverse on the right for \( P \) as \( P_{Q(f)} \) is equal to the map \( p \mapsto p f_y(\text{refl}_y) \), and by induction on \( p : y = x \), \( p f_y(\text{refl}_y) = f_y(p) \) (indeed this is true for \( p \equiv \text{refl}_y \)). This means that \( P_{Q(f)} = f \). Next, we show that \( Q \) is an inverse on the left for \( P \): indeed for any \( q : y = z \) \( P_q(\text{refl}_y)^{-1} = (\text{refl}_y q^{-1})^{-1} = q \); in other words \( Q(P_q) = q \).

**Theorem 4.8.6.** If \( G \) is a group (or \( \infty \)-group), then the function

\[
P : BG \to (\text{Torsor}_G, \text{Pr}_G), \quad z \mapsto P_z \equiv (x \mapsto (z =_{BG} x))
\]

is an equivalence. Univalence then allows us to derive an identity

\[
\bar{P} : G \cong \text{Aut}_{\text{Set}}(\text{Pr}_G)
\]

of groups (or \( \infty \)-groups).

**Proof.** Since both \( \text{Torsor}_G \) and \( BG \) are connected, it suffices by Corollary 2.17.9 to show that each \( \text{ap}_p : (y = z) \to (P_y = P_z) \) is an equivalence. One prove first that \( \text{ap}_p \) is indeed equal to the function

\[
P : (y = z) \to (P_y = P_z)
\]

made explicit in Example 4.8.4. It is done by induction on \( q : y = z \), as indeed

\[
\text{ap}_p(\text{refl}_y) \equiv \text{refl}_{P_y} = (p \mapsto p \text{refl}_y^{-1}).
\]

Then Lemma 4.8.5 states exactly that \( \text{ap}_p \) is an equivalence. \( \square \)

### 4.8.7 Homomorphisms and torsors

In view of the equivalence \( P^G \) between \( BG \) and \( (\text{Torsor}_G, \text{Pr}_G) \) of Theorem 4.8.6 one might ask what a group homomorphism \( f : \text{Hom}(G, H) \) translates to on the level of torsors. Off-hand, the answer is \( (P^f)^{-1} \), but we can be more concrete than that. We do know that for \( x : BG \) the \( G \)-torsor \( P^G \) should be sent to \( P^f \), but how do we express this for an arbitrary \( G \)-torsor?
Definition 4.8.8. Let \( f : \text{Hom}(G, H) \) be a group homomorphism. If \( Y : BH \to \text{Set} \) is an \( H \)-set then the restriction \( f^*Y \) of \( Y \) to \( G \) is the \( G \)-set given by precomposition

\[
f^*Y \equiv Y f : BG \to \text{Set}.
\]

If \( X : BG \to \text{Set} \) is a \( G \)-set and \( y : BH \) define the induced \( H \)-type \( f_*BH \to \mathcal{U} \) by

\[
f_*X(y) \equiv \sum_{x : BG} (Bf x = y) \times X(x).
\]

For \( X \) being the principal \( G \)-torsor \( \text{Pr}_G \), the contraction of \( \sum_{x : BG} (\text{sh}_G = x) \) induces an equivalence

\[
\eta_y : f_*\text{Pr}_G(y) = \sum_{x : BG} (Bf(x) = y) \times (\text{sh}_G = x) \cong (Bf(x) = y) \equiv \text{Pr}_{Bf(x)}^H(y).
\]

The resulting identity \( \bar{\eta} : f_*\text{Pr}_G = \text{Pr}_{Bf(x)}^H \) shows that for every \( G \)-torsor \( X \) the \( H \)-type \( f_*X \) is an \( H \)-torsor.

Summing up:

Lemma 4.8.9. Let \( f : \text{Hom}(G, H) \) be a group homomorphism. If \( X \) is a \( G \)-torsor, then the induced \( H \)-type \( f_*X \) is an \( H \)-torsor and so we get an induced map

\[
f_* : \text{Torsor}_G \to \text{Torsor}_H.
\]

The identity \( \bar{\eta} : f_*\text{Pr}_G = \text{Pr}_{Bf(x)}^H \) shows that

\[
\begin{array}{ccc}
BG & \xrightarrow{Bf} & BH \\
\downarrow{p_U} & & \downarrow{p_U} \\
\text{Torsor}_G & \xrightarrow{f_*} & \text{Torsor}_H
\end{array}
\]

commutes.

Remark 4.8.10. Notice that our construction of the induced \( G \)-set works equally well for a homomorphism \( \phi : \text{Hom}^{\text{abs}}(\text{abs}(G), \text{abs}(H)) \) : if \( X : BG \to \text{Set} \) is a \( G \)-set, then we define the \( H \)-set \( \phi_*X : BH \to \text{Set} \) by

\[
\phi_*X(y) \equiv (\text{sh}_H = y) \times_{UG} X(\text{sh}_G)
\]

to be the set quotient of \( (\text{sh}_H = y) \times X(\text{sh}_G) \) by the relation \( (p, x) \sim (p \phi(q)^{-1}, X(q)x) \) for all \( q : \text{sh}_G = pt_G \). Just as above, for \( X \) the principal \( G \)-torsor we get an identity \( \eta_\phi : \phi_*\text{Pr}_G = \text{Pr}_H \) which, when evaluated at \( y : BH \), corresponds under univalence to the equivalence

\[
(\text{sh}_H = y) \times_{UG} UG \to (\text{sh}_H = y)
\]

sending \([p, q] : (\text{sh}_H = y) \times_{UG} UG\) to \( p \phi(q) : (\text{sh}_H = y)\).

4.9 Groups; concrete vs. abstract

We use Theorem 4.8.6 as our inspiration for trying to construct a group from an abstract group. That is, in total analogy, we define the torsors for an abstract group, and it will then be a relative simple matter to show that the processes of

(1) forming the abstract group of a group and

Note that we have not considered an “abstract” counterpart of the concept of \( \infty \)-group, so all we do in this section is set-based.
(2) taking the group represented by the torsors of an abstract group are inverse to each other.

**Definition 4.9.1.** If \( G = (S, e, \mu, i) \) is an abstract group, a \( G \)-set is a set \( X \) together with a homomorphism \( G \to \text{abs}(\Sigma X) \) from \( G \) to the (abstract) permutation group of \( X \):

\[
\text{Set}^{\text{abs}}_G := \sum_{X \in \text{Set}} \text{Hom}(G, \text{abs}(\Sigma X)).
\]

The *principal* \( G \)-torsor \( \text{Pr}^{\text{abs}}_G \) is the \( G \)-set consisting of the underlying set \( S \) together with the homomorphism \( G \to \text{abs}(\Sigma_S) \) with underlying function of sets \( S \mapsto (S = S) \) given by sending \( g : S \) to \( u(a) \mapsto s \cdot g^{-1} \).

The type of \( G \)-torsors is

\[
\text{Torsor}^{\text{abs}}_G := \sum_{S : \text{Set}^{\text{abs}}_G} ||\text{Pr}^{\text{abs}}_G = S||.
\]

**Example 4.9.2.** If \( G \) is a group we can unravel the definition and see that an \( \text{abs}(G) \)-set consists of

1. a set \( S \),
2. a function \( f : UG \to (S = S) \)
3. such that \( f(e_G) = \text{refl}_S \) and for all \( p, q : UG \) we have that \( f(p \cdot q) = f(p) \cdot f(q) \).

To help reading the coming proofs we introduce some notation that is redundant, but may aid the memory in cluttered situations: Let \( x, y, z \) be elements in some type, then

\[
\text{preinv} : (y = x) \to ((y = z) = (x = z)), \quad \text{preinv}(q)(p) \equiv P_q p \equiv p q^{-1}
\]

\[
\text{post} : (y = z) \to ((x = y) = (x = z)), \quad \text{post}(p)(q) \equiv \text{post}_p q \equiv p q
\]

**Example 4.9.3.** If \( G \) is a group, then for any \( x : \text{BG} \) the principal \( G \)-torsor *evaluated at* \( x \), i.e., the set \( \text{Pr}_{\Sigma x} := (\text{sh}_G = x) \), has a natural structure of an \( \text{abs}(G) \)-set by means of

\[
\text{preinv} : UG \to ((\text{sh}_G = x) = (\text{sh}_G = x))
\]

and the fact that \( \text{preinv}(e_G) := \text{refl}_{\text{sh}_G = x} \) and that for \( p, q : UG \) we have that

\[
\text{preinv}(p \cdot q) = \text{preinv}(p) \cdot \text{preinv}(q).
\]

That this \( \text{abs}(G) \)-set is an \( \text{abs}(G) \)-torsor then follows since \( \text{BG} \) is connected (any \( \text{sh}_G = x \) will serve as a proof of \( (\text{sh}_G = x, \text{preinv}, !) \) is \( \text{Pr}^{\text{abs}}_{\text{abs}(G)} \)).

Though it sounded like we made a choice ending up with \( \text{preinv} \); we really didn’t – it is precisely what happens when you abstract the homomorphism \( G \to \Sigma_{\text{Pr}_G} \): you get the function of identity types

\[
UG \to (\text{Pr}_G(x) = \text{Pr}_G(x))
\]

which by the very definition of transport for \( \text{Pr}_G \) is \( \text{preinv} \).
**Definition 4.9.4.** If $G$ is an abstract group, then the concrete group $\text{concr}(G)$ associated with $G$ is the group given by the pointed connected groupoid $(\text{Torsor}_{G}^{\text{abs}}, \text{Pr}_{G})$.

We give the construction of Example 4.9.3 a short name since it will occur in important places.

**Definition 4.9.5.** Let $G$ be a group. The group homomorphism

$$q_{G} : \text{Hom}(G, \text{concr}(\text{abs}(G)))$$

is defined in terms of the pointed map by the same name

$$q_{G} : BG \to (\text{Torsor}_{\text{abs}(G)}^{\text{abs}}, \text{Pr}_{\text{abs}(G)}), \quad q_{G}(z) = (\text{Pr}_{G}(z), \text{preinv}, !).$$

**Lemma 4.9.6.** For all groups $G$, the pointed function $q_{G} : G \to \text{concr}(\text{abs}(G))$ is an equivalence.

**Proof.** To prove that $q_{G}$ is an equivalence it is, by Corollary 2.17.9(2), enough to show that if $x, y : BG$ then the induced map

$$q_{G} : (x \equiv_{BG} y) \to (q_{G}(x) = q_{G}(y))$$

is an equivalence. Now, $q_{G}(x) = q_{G}(y)$ is equivalent to the set

$$\left((\text{sh}_{G} = x), \text{preinv}\right) =_{\text{abs}(G)-\text{set}} \left((\text{sh}_{G} = y), \text{preinv}\right)$$

which in turn is equivalent to

$$\sum_{f : (\text{sh}_{G} = x)} \text{preinv} = \text{preinv} f$$

($\text{preinv} = \text{preinv} f$ is shorthand for $\prod_{q : \text{sh}_{G} = x} \prod_{p : \text{sh}_{G} = p} f(p q^{-1}) = f(p) q^{-1}$ and the rest of the data is redundant at the level of symmetries) and under these identities $q_{G}$ is given by

$$(\text{post, !}) : (x = y) \to \sum_{f : (\text{sh}_{G} = x)} \text{preinv} = \text{preinv} f.$$ 

Given an element $(f, !) : \sum_{f : (\text{sh}_{G} = x)} \text{preinv} = \text{preinv} f$, the preimage $(\text{post, !})^{-1}(f, !)$ is equivalent to the set $\sum_{r : x = y}(f = \text{post}_{r})$. But if $(r, !), (s, !) : \sum_{r : x = y}(f = \text{post}_{r})$, then for all $p : \text{sh}_{G} = x$ we get that $r p = f(p) = s p$, that is $r = s$, so that the preimage is in fact a proposition. To show that the preimage is contractible, it is enough to construct a function $(\text{sh}_{G} = x) \to \sum_{r : x = y}(f = \text{post}_{r})$, and sending $p$ to $f(p) p^{-1}$ will do.

**Example 4.9.7.** Let $G = (S, e, \mu, !)$ be an abstract group. Then the underlying set of $\text{abs}(\text{concr}(G))$ is $\text{Pr}_{G}^{\text{abs}} = \text{Torsor}_{G}^{\text{abs}} \text{Pr}_{G}^{\text{abs}}$. Unraveling the definitions we see that this set is equivalent to

$$\sum_{p : S} \prod_{q, s : S} (p(s q^{-1}) = p(s) q^{-1}).$$

Setting $s \equiv e$ and renaming $t \equiv q^{-1}$ in the last equation, we see that $p(t) = p(e) t$; that is $p$ is simply multiplication with an element $p(e) : S$. In other words, the function

$$r_{G} : S \to \sum_{p : S} \prod_{q, s : S} (p(s q^{-1}) = p(s) q^{-1}), \quad r_{G}(u) \equiv (u, !).$$
is an equivalence of sets, which we by univalence is converted into an identity. The abstract group structure of \( \text{abs}(\text{concr}(G)) \) is given by it being the symmetries of \( \text{Pr}_G^{\text{abs}} \); translated to \( \sum_{p:S} \prod_{q,s:S} (p(s \cdot q^{-1}) = p(s) \cdot q^{-1}) \) this corresponds via the first projection to the symmetries of \( S \). This means that we need to know that if \( u, v : S \) and consider the two symmetries \( u \cdot v : S \) and then their composite (the operation on the symmetry on \( S \)) is equal to \( (u \cdot v) : S \) (the abstract group operation), but this is true by associativity \( (u \cdot (v \cdot s)) = (u \cdot v) \cdot s \). That \( r_G \) also sends \( e : S \) to \( \text{refl}_S \) is clear. Hence our identity \( r_G \) underlies an identity of abstract groups
\[
r_G : G = \text{Group}^{\text{abs}} \text{abs}(\text{concr}(G)).
\]

This shows that every abstract group encodes the symmetries of something essentially unique. Summing up the information we get

**Theorem 4.9.8.** Let \( G \) be an abstract group. Then
\[
\text{abs} : \text{Group} \to \text{Group}^{\text{abs}}
\]
is an equivalence.

### 4.10 Homomorphisms; abstract vs. concrete

Now that we know that the type of groups is identical to the type of abstract groups, it is natural to ask if the notion of group homomorphisms also coincide.

They do, and we provide two independent and somewhat different arguments. Translating from group homomorphisms to abstract group homomorphisms is easy: if \( G \) and \( H \) are groups, then we defined
\[
\text{abs} : \text{Hom}(G, H) \to \text{Hom}^{\text{abs}}(\text{abs}(G), \text{abs}(H))
\]
in Definition 4.4.20 as the function which takes a homomorphism, aka a pointed map \( f = (Bf, p_f) : BG \to BH \) to the induced map of identity types
\[
Uf := \text{ad}_{p_f} \cdot \text{ap}_{Bf} : UG \to UH
\]
together with the proofs that this is an abstract group homomorphism from \( \text{abs}(G) \) to \( \text{abs}(H) \), c.f Definition 4.4.20.

Going back is somewhat more involved, and it is here we consider two approaches. The first is a compact argument showing directly how to reconstruct a pointed map \( Bf : BG \to BH \) from an abstract group homomorphism from \( \text{abs}(G) \) to \( \text{abs}(H) \), the second translates back and forth via our equivalence between abstract and concrete groups.

The statement we are after is

**Lemma 4.10.1.** If \( G \) and \( H \) are groups, then
\[
\text{abs} : \text{Hom}(G, H) \to \text{Hom}^{\text{abs}}(\text{abs}(G), \text{abs}(H))
\]
is an equivalence.

and the next two subsections offer two proofs.
"Delooping" a group homomorphism

We now explore the first approach. It might be helpful to review Lemma 3.4.9 for a simple example of delooping in the special case of the circle. Here we elaborate the general case.

Proof. Suppose we are given an abstract group homomorphism

\[ f : \text{Hom}^{\text{abs}}(\text{abs}(G), \text{abs}(H)) \]

and we explain how to build a map \( g : BG \to BH \) with a path \( p : \text{sh}_H = g(\text{sh}_G) \) such that \( pf(\omega) = g(\omega)p \) for all \( \omega : \text{sh}_G = \text{sh}_G \) (so that \( g \) is a "delooping" of \( f \), that is, \( f = \text{abs}(g) \)).

To get an idea of our strategy, let us assume the problem solved. The map \( g : BG \to BH \) will then send any path \( x : \text{sh}_G = x \) to a path \( \alpha(\omega) : g(\text{sh}_G) = g(x) \) and so we get a family of paths \( p(\alpha) : g(\omega)p in \text{sh}_H = g(x) \) such that

\[ p(\alpha \omega) = g(\omega)p = g(\alpha)p(\omega) = p(\alpha)f(\omega) \]

for all \( \omega : \text{sh}_G = \text{sh}_G \) and \( \alpha : \text{sh}_G = x \).

This suggests to introduce the following family

\[ C(x) := \sum_{y : BH} \sum_{p : (\text{sh}_G = x) \to (\text{sh}_H = y)} \prod_{\omega : \text{sh}_G = \text{sh}_G} \prod_{x : \text{sh}_G = x} p(\alpha \omega) = p(\alpha)f(\omega) \]

An element of \( C(x) \) has three components, the last component being a proposition since \( BH \) is a groupoid.

The type \( C(\text{sh}_G) \) has a simpler description. An element of \( C(\text{sh}_G) \) is a pair \( y, p \) such that \( p(\alpha \omega) = p(\alpha)f(\omega) \) for \( \alpha \) and \( \omega \) in \( \text{sh}_G = \text{sh}_G \). Since \( f \) is an abstract group homomorphism, this condition can be simplified to \( p(\omega) = p(1_{\text{sh}_G})f(\omega) \), and the map \( p \) is completely determined by \( p(1_{\text{sh}_G}) \). Thus \( C(\text{sh}_G) \) is equal to \( \sum_{y : BH} \text{sh}_H = y \) and is contractible.

It follows that we have

\[ \prod_{x : BG} (\text{sh}_G = x) \to \text{isContr} C(x) \]

and so, since \( \text{isContr} C(x) \) is a proposition

\[ \prod_{x : BG} \|a = x\| \to \text{isContr} C(x) \]

Since \( BG \) is connected, we have \( \prod_{x : BG} \text{isContr} C(x) \) and so, in particular, we have an element of \( \prod_{x : BG} C(x) \).

We get in this way a map \( g : BG \to BH \) together with a map \( p : (a = x) \to (\text{sh}_H = g(x)) \) such that \( p(\alpha \omega) = p(\alpha)f(\omega) \) for all \( \alpha \) in \( \text{sh}_G = x \) and \( \omega \) in \( \text{sh}_G = \text{sh}_G \). We have, for \( a : \text{sh}_G = x \)

\[ \prod_{x' : BG} \prod_{\lambda : x = x'} p(\lambda a) = g(\lambda)p(\alpha) \]

since this holds for \( \lambda = 1_x \). In particular, \( p(\omega) = g(\omega)p(1_{\text{sh}_G}) \).

We also have \( p(\omega) = p(1_{\text{sh}_G})f(\omega) \), hence \( p(1_{\text{sh}_G})g(\alpha) = f(\alpha)p(1_{\text{sh}_G}) \) for all \( \alpha : \text{sh}_G = \text{sh}_G \) and we have found a delooping of \( f \).
The concrete vs. abstract homomorphisms via torsors.

The second approach to Lemma 4.10.1 is as follows:

Proof. The equivalence of $P^G : BG \xrightarrow{\sim} (\text{Torsor}_G, \Pr_G)$ of Theorem 4.8.6 gives an equivalence

$$P : \text{Hom}(G, H) \xrightarrow{\sim} ((\text{Torsor}_G, \Pr_G) \rightarrow, (\text{Torsor}_H, \Pr_H))$$

Consider the map

$$A : ((\text{Torsor}_G, \Pr_G)) \rightarrow, (\text{Torsor}_H, \Pr_H) \rightarrow \text{Hom}^{\text{abs}}(\text{abs}(G), \text{abs}(H))$$

given by letting $A(f, p)$ be the composite

\[
\begin{array}{ccc}
\text{UG} & \xrightarrow{p^G} & \text{UH} \\
\downarrow{f} & & \downarrow{p^H} \\
(\Pr_G = \Pr_G) & \xrightarrow{(f \Pr_G = f \Pr_G)} & (\Pr_H = \Pr_H)
\end{array}
\]

(together with the proof that this is an abstract group homomorphism). We are done if we show that $A$ is an equivalence.

If $(\phi, !) : \text{Hom}^{\text{abs}}(\text{abs}(G), \text{abs}(H))$ and $X : BG \rightarrow \text{Set}$ is a $G$-torsor, recall the induced $H$-torsor $\phi, X$ from Remark 4.8.10 and the identity $\eta_\phi : \phi, \Pr_G = \Pr_H$. Let

$$B : \text{Hom}^{\text{abs}}(\text{abs}(G), \text{abs}(H)) \rightarrow ((\text{Torsor}_G, \Pr_G) \rightarrow, (\text{Torsor}_H, \Pr_H))$$

be given by $B(\phi, !) = (\phi, X, \eta_\phi)$.

We show that $A$ and $B$ are inverse equivalences. Given an abstract group homomorphism $(\phi, !) : \text{Hom}^{\text{abs}}(\text{abs}(G), \text{abs}(H))$, then $AB(\phi, !)$ has as underlying set map

\[
\begin{array}{ccc}
\text{UG} & \xrightarrow{\phi^G} & \text{UH} \\
\downarrow{\phi_H} & & \downarrow{\phi^H} \\
(\Pr_G = \Pr_G) & \xrightarrow{(\phi, \Pr_G = \phi, \Pr_G)} & (\Pr_H = \Pr_H)
\end{array}
\]

and if we start with a $g : \text{UG}$, then $p^G$ sends it to $p^G \equiv \text{preinv}(g)$. Furthermore, $\phi, \text{preinv}(g)$ is $[\text{id}, \text{preinv}(g)]$ which is sent to $\text{preinv}(\phi(g))$ in $\Pr_H = \Pr_H$ which corresponds to $\phi(g) : \text{UH}$ under $P^H$. In other words, $AB(\phi, !) = (\phi, !)$. The composite $BA$ is similar. \hfill \Box

### 4.11 Monomorphisms and epimorphisms

In set theory we say that a function $f : B \rightarrow C$ of sets is an injection if for all $b, b' : B$ we have that $f(b) = f(b')$ implies that $b = b'$. This conforms with our definitions. Furthermore, since giving a term $b : B$ is equivalent to giving a (necessarily constant) function $c_b : 1 \rightarrow B$, we could alternatively say that a function $f : B \rightarrow C$ is an injection if and only if for any two $g, h : 1 \rightarrow B$ such that $fg = fh$ we have that $g = h$. In fact, by function extensionality we can replace $1$ by any set $A$ (two functions are identical if and only if they have identical values at every point).

Similarly, a function $f : B \rightarrow C$ is surjective if for all $c : C$ the preimage $f^{-1}(c) = \sum_{b : B} c = f(b)$ is non-empty. A smart way to say this is to say

The reason to complicate $\text{abs}$ this way is that it gets easier to write out the inverse function.
that the first projection from $\sum_{c \in C} f^{-1}(c)$ to $C$ is an equivalence. Since $B$ is always equivalent to $\sum_{c \in C} f^{-1}(c)$, we see that for a surjection $f : B \to C$ and family of propositions $P : C \to \text{Prop}$, the propositions $\prod_{c \in C} P(c)$ and $\prod_{b \in B} Pf(b)$ are equivalent. In particular, if $g, h : C \to D$ are two functions into a set $D$ the proposition $\prod_{c \in C} (g(c) = h(c))$ is equivalent to $\prod_{b \in B} (gf(b) = hf(b))$.

From this we condense the following characterizations of injections and surjections of sets which will prove to generalize nicely to other contexts.

**Lemma 4.11.1.** Let $f : B \to C$ be a function between sets.

1. The function is an injection of and only if for any set $A$ and functions $g, h : A \to B$,

$$
\begin{array}{c}
A \\
\downarrow^g \\
\rightarrow B \\
\rightarrow_C \\
\downarrow^h \\
A \\
\end{array}
\xrightarrow{f}

\begin{array}{c}
A \\
\downarrow^g \\
\rightarrow B \\
\rightarrow_C \\
\downarrow^h \\
A \\
\end{array}
\xrightarrow{f}

\begin{array}{c}
A \\
\downarrow^g \\
\rightarrow B \\
\rightarrow_C \\
\downarrow^h \\
A \\
\end{array}
\xrightarrow{f}

then $fg = fh : A \to C$ implies $g = h$.

2. The function is an injection of and only if for any set $D$ and functions $g, h : C \to D$,

$$
\begin{array}{c}
B \\
\downarrow^f \\
\rightarrow C \\
\rightarrow_D \\
\downarrow^g \\
B \\
\end{array}
\xrightarrow{f}

\begin{array}{c}
B \\
\downarrow^f \\
\rightarrow C \\
\rightarrow_D \\
\downarrow^g \\
B \\
\end{array}
\xrightarrow{f}

\begin{array}{c}
B \\
\downarrow^f \\
\rightarrow C \\
\rightarrow_D \\
\downarrow^g \\
B \\
\end{array}
\xrightarrow{f}

then $gf = hf : A \to C$ implies $g = h$.

By Lemma 4.11.1 there is a pleasing reformulation which highlights that injections/surjections of sets are characterized by injections of sets of functions: a function of sets $f : B \to C$ is

1. an injection if and only if for any set $A$ postcomposition by $f$ given an injection from $A \to B$ to $A \to C$

2. a surjection if and only if for any set $D$ precomposition by $f$ gives an injection from $B \to D$ to $B \to D$.

This observation about sets translates fruitfully to other contexts and in particular to groups. To make it clear that we talk about group homomorphisms (and not about the underlying unpointed functions of connected groupoids) we resort to standard categorical notation.

**Definition 4.11.2.** Given groups $G, H$, a homomorphism $f : \text{Hom}(G, H)$ is called a

1. monomorphism if for any group $F$, postcomposition by $f$ is an injection from $\text{Hom}(F, G)$ to $\text{Hom}(F, H)$, and an

2. epimorphism if for any group $I$, precomposition by $f$ is an injection from $\text{Hom}(H, I)$ to $\text{Hom}(G, I)$.

The corresponding families of propositions are called

$$
\text{isMono}, \text{isEpi} : \text{Hom}(G, H) \to \text{Prop}
$$

We’ve seen that for any group $G$, the underlying set $U_G \equiv (\text{sh}_G = \text{sh}_C)$ of $\text{abs}(G)$ is equivalent to the set of homomorphisms $\text{Hom}(Z, G)$ which in turn is equivalent to the set of abstract homomorphisms $\text{Hom}^{\text{abs}}(\text{abs}(Z), \text{abs}(G))$ and that abstraction preserves composition.
Hence, if \( f : \text{Hom}(G, H) \) is a group homomorphism, then saying that \( Uf \) is an injection is equivalent to saying that postcomposition by \( f \) is an injection \( \text{Hom}(Z, G) \to \text{Hom}(Z, H) \). In this observation, the integers \( Z \) plays no more of a rôle than 1 does in Lemma 4.11.1; we can let the source vary over any group \( F \):

**Lemma 4.11.3.** Let \( G \) and \( H \) be groups and \( f : \text{Hom}(G, H) \) a homomorphism. The following propositions are equivalent:

1. \( f \) is a monomorphism;
2. \( Uf : UG \to UH \) is an injection;
3. \( Bf : BG \to BH \) is a set bundle.

**Proof.** We have already seen that condition (1) implies condition (2) (let \( F = \mathbb{Z} \)). Conversely, suppose that (2) holds and \( F \) is a group. Consider the commutative diagram

\[
\begin{array}{c}
\text{Hom}(F, G) \\
\downarrow \quad \downarrow \quad \downarrow \\
\text{Hom}(F, H)
\end{array}
\]

\[
\begin{array}{rcl}
\text{Hom}(\mathbb{Z}, F) \to \text{Hom}(\mathbb{Z}, G) & \to & \text{Hom}(\mathbb{Z}, F) \to \text{Hom}(\mathbb{Z}, H),
\end{array}
\]

where the vertical maps are the injections from the sets of (abstract) homomorphism to the sets of functions of underlying sets and the horizontal maps are postcomposition with \( f \). Since the bottom function is by assumption is an injection, so is the upper one. \(^{34}\)

The equivalence of (3) and (2) follows immediately from Corollary 2.17.9(1), using that \( BG \) is connected and \( f \) is pointed and the equivalence between \( \text{Hom}(G, H) \) and \( BG \to * \).

Similarly, we have:

**Lemma 4.11.4.** The following propositions are equivalent:

1. \(^{34}\) \( f \) is an epimorphism;
2. \( Uf : UG \to UH \) is a surjection.
3. \( Bf : BG \to BH \) has connected fibers.

**Proof.** The equivalence of (2) and (3) is immediate.

For the rest, the easy direction is that (2) implies (1): (TODO)

The harder direction, that (1) implies (2), is a corollary of the following lemma, which states that monos are equalizers. Indeed, we can factor any \( f : \text{Hom}(G, H) \) via the image as a surjection followed by a mono:

\[
G \xrightarrow{\eta} \text{im}(f) \xrightarrow{i} H
\]

If \( f \) is an epi, then so is \( i \). But \( i \) is an equalizer,

\[
\text{im}(f) \xrightarrow{i} H \xrightarrow{\psi} L,
\]

so as an epi, \( \psi i = \psi i \) implies \( \psi = \psi \), so \( i \) is an equalizer of already equal homomorphisms, so \( i \) is an isomorphism, which implies that \( f \) is surjective.

\(^{34}\)Alternatively: and \( g, h : \text{Hom}(G, H) \). Then \( fg = fh \) implies that for all \( p : \text{Hom}(Z, F) \) we have by associativity that \( (gp) = (fg)p = (fh)p = (hp) \), and so, by assumption, that \( gp = hp \). Again, by function extensionality (of functions \( \text{Hom}(Z, F) \to \text{Hom}(Z, G) \)), this is exactly saying that \( Ug \) is identical to \( Uh \).

\(^{35}\)This proof follows an idea by Trimble \(^{36}\).

Lemma 4.11.5. Every monomorphism \( i : H \to G \) is an equalizer.\(^{35}\)

Proof draft. Consider the projection \( \pi : G \to G/H \) to the set of cosets. Let \( j : G/H \to A \) be an injection into a group \( A \). (We could for instance let \( A \) be the free (abelian) group on \( G/H \). [Add xref to statement that inclusion of generators in an injection.])

Consider the group \( W \equiv \text{Aut}_E(\text{sh}_G, \text{cst}_{shG}) \), where

\[
E \equiv \sum_{t \in G} ((\text{sh}_G \to t) \to BA).
\]

We have two homomorphisms \( \varphi, \psi : G \to W \) with the same underlying map, \( t \mapsto (t, \text{cst}_{shG}) \), but with different pointing paths:

\[
\varphi_{pt} \equiv \text{refl}_{shG, \text{cst}_{shG}}, \quad \psi_{pt} \equiv (\text{refl}_{shG}, j \pi).
\]

The equalizer of \( \varphi \) and \( \psi \) thus consists of all \( g : U \) such that \( j \pi(g g') = j \pi(g') \) for all \( g' : U \). Since \( j \) is injective, this is equivalent to \( \pi(g g') = \pi(g') \) for all \( g' : U \), and this holds if and only if \( g \) belongs to \( H \).

\[\square\]

4.11.6 Any symmetry is a symmetry in \( \text{Set} \)

The correspondence between groups and abstract groups allows for a cute proof of what is often stated as “any group is a permutation group”, which in our parlance translates to “any symmetry is a symmetry in \( \text{Set} \)”.

Recall the principal \( G \)-torsor \( \text{Pr}_G : BG \to \text{Set} \). Since \( \text{Pr}_G(\text{sh}_G) := UG \)

this defines a pointed function \( \rho_G : BG \to \text{Set}(U_G) \equiv (\text{Set}(U_G), UG) \), i.e., a homomorphism from \( G \) to the permutation group

\( \rho_G : \text{Hom}(G, \Sigma_{U_G}) \).

Theorem 4.11.7 (Cayley). Let \( G \) be a group. Then \( \rho_G : \text{Hom}(G, \Sigma_{U_G}) \) is a monomorphism.

Proof. In view of Lemma 4.11.3 we need to show that \( \rho_G : BG \to \text{Set}_{(U_G)} \)

is a set bundle. Under the identity

\[
\tilde{P} : BG = (\text{Torsor}_G, \text{Pr}_G) \equiv (\text{Set}_{(U_G)}, UG)
\]

of Theorem 4.8.6, \( \rho_G \) translates to the evaluation map

\[
\text{ev}_{shG} : (BG \to \text{Set})_{(ptG)} \to \text{Set}_{(U_G)}, \quad \text{ev}_{shG}(E) = E(\text{sh}_G).
\]

We must show that the preimages \( \text{ev}_{shG}^{-1}(X) \) for \( X : \Sigma_{U_G} \) are sets. This fiber is equivalent to \( \sum_{E : (BG \to \text{Set})_{(ptG)}} (X = E(\text{sh}_G)) \) which is a set precisely when \( \sum_{E : BG \to \text{Set}} (X = E(\text{sh}_G)) \) is a set. We must then show that if \( (E, p), (F, q) : \sum_{E : BG \to \text{Set}} (X = E(\text{sh}_G)) \), then the type \( (E, p) = (F, q) \), which is equivalent to

\[
\prod_{x : BG} \sum_{\phi(x) : E(x) = F(x)} \phi(\text{sh}_G) = qp^{-1},
\]

is a proposition. If \( \phi, \psi : ((E, p) = (F, q)) \), we must show that \( \phi = \psi \) and since that for \( x : BG \) both \( E(x) \) and \( F(x) \) are sets, it is enough to show that the proposition \( \phi(x) = \psi(x) \) is not empty. Let \( f : (\text{sh}_G = x) \to

Note that if \( r : \text{sh}_G = x \), then \( \phi(x) = F(r)qp^{-1}E(r)^{-1} \), in a picture

\[
\begin{array}{ccccccc}
E(ptG) & \xrightarrow{E(r)} & E(x) \\
\phi(ptG) & \xrightarrow{\phi(r)} & \phi(x) \\
\phi(x) & \xrightarrow{F(\text{sh}_G)} & F(x) \\
\end{array}
\]

and so \( \phi(x) \) (which by nature is independent of such an \( r : \text{sh}_G = x \)) is uniquely determined by \( (E, p) \) and \( (F, q) \). The text says this formally.
Lemma: Center is subgroup

\[ (\phi(x) = \psi(x)) \text{ be given by letting } f(r) \text{ be the composite of the identities } \phi(x) = F(r)\psi^{-1}E(r)^{-1} = \psi(x) \text{ given above. Since } BG \text{ is connected, and } \phi(x) = \psi(x) \text{ is a proposition, one can consider that } sh_G = x \text{ is not empty, and we are done.} \]

\[ \square \]

4.12 Abelian groups

Recall that given a pointed type \( X \), we coerce it silently to its underlying unpointed type \( X \) whenever this coercion can be inferred from context. For example, given a group \( G \), the type \( BG \cong BG \) can not possibly mean anything but \( BG \cong BG \) as the operator \( \cong \) acts on bare types. To refer to the type of pointed equivalences (that is the pointed functions whose underlying functions are equivalences), we shall use the notation \( BG \cong BG \).

4.12.1 Center of a group

**Definition 4.12.2.** Let \( G \) be a group. The center of \( G \), denoted \( Z(G) \), is the group \( Aut_{BG} (BG, refl_{BG}) \).

There is a natural map \( ev_{shG} : (BG, \rightarrow BG) \rightarrow BG \) defined by \( ev_{shG}(\varphi) \equiv \varphi(sh_G) \), where the path \( \varphi \) is coerced to a function through univalence. In particular, \( ev_{shG}(refl_{BG}) \equiv sh_G \). It makes the restriction of this map to the connected component of \( refl_{BG} \) a pointed map. In other words, it defines a group homomorphism

\[ z_G : Hom(Z(G), G). \]

such that \( Bz_G : \equiv ev_{shG} \). We will now justify the name center for \( Z(G) \), and connect it to the notion of center for abstract groups in ordinary mathematics. The homomorphism \( z_G \) induces a homomorphism of abstract groups from \( abs(Z(G)) \) to \( abs(G) \). By induction on \( p : refl_{BG} \rightarrow \varphi \) for \( \varphi : BG \rightarrow BG \), one proves that \( ap_{Bz_G}(p) = p(sh_G) \): indeed, this is true when \( p \equiv refl_{refl_B} \). One proves furthermore, again by induction on \( p : refl_{BG} \rightarrow \varphi \), that \( ap_{\varphi} (q \mapsto p(sh_G)^{-1} q p(sh_G)) \). In particular, when \( \varphi \equiv refl_{refl_B} \), it shows that for every \( p : refl_{BG} \rightarrow refl_{BG} \), the following proposition holds:

\[ \prod_{g : UG} p(sh_G)g = gp sh_G \]

In other words, \( abs(z_G) \) maps elements of \( abs(Z(G)) \) to elements of \( abs(G) \) that commute with every other elements. (The set of these elements is usually called the center of the group \( abs(G) \) in ordinary group theory.)

**Lemma 4.12.3.** The map \( Bz_G \) is a set bundle over \( BG \).

**Proof.** One wants to prove the proposition \( isSet((Bz_G)^{-1}(x)) \) for each \( x : BG \). By connectedness of \( BG \), it reduces to showing the proposition only at \( x \equiv sh_G \). However,

\[ (Bz_G)^{-1}(sh_G) \equiv \sum_{\varphi : BZ(G)} sh_G \rightarrow \varphi(sh_G) \]

Recall that \( BZ(G) \) is the connected component of \( refl_{BG} \) in \( BG \rightarrow BG \).

In particular, if \( (\varphi, p) \) and \( (\psi, q) \) are two elements of the type on the right
hand-side above, the characterization of identity types in sum types
gives an equivalence:

\[((\varphi, p) \overset{\cong}{\rightarrow} (\psi, q)) \overset{\cong}{\rightarrow} \sum_{\pi: \varphi \rightarrow \psi} \pi(\text{sh}_G)p = q.\]

We shall prove that the type on the right is a proposition, and it goes as follows:

1. for \(\pi: \varphi \overset{\cong}{\rightarrow} \psi\), the type \(\pi(\text{sh}_G)p = q\) is a proposition; hence

   \(\sum_{\pi: \varphi \overset{\cong}{\rightarrow} \psi} \pi(\text{sh}_G)p = q\) is a subset of the set \(\varphi \overset{\cong}{\rightarrow} \psi\), so for elements

   \((\pi, !)\) and \((\pi', !)\) of the subset, we have to prove \(\pi = \pi'\),

2. because \(\pi = \pi'\) is a proposition, by connectedness of \(BG\), it is enough

   to prove \(\pi(\text{sh}_G) = \pi'(\text{sh}_G)\),

3. finally the propositional condition on \(\pi\) and \(\pi'\) allows us to conclude

   \(\pi(\text{sh}_G) = qp^{-1} = \pi'(\text{sh}_G)\).

\[\square\]

**Corollary 4.12.4.** The induced map \(\text{abs}(z_G): \text{abs}(Z(G)) \rightarrow \text{abs}(G)\) is injective.

The following result explains how every element of the “abstract center” of \(G\) is picked out by \(\text{abs}(z_G)\).

**Lemma 4.12.5.** Let \(g: UG\) and suppose that \(gh = hg\) for every \(h: UG\). The fiber \((\text{ap}_{\text{BG}})^{-1}(g)\) contains an element.

**Proof.** One must construct an element \(\hat{g}: \text{refl}_{BG} = \text{refl}_{BG}\) such that \(g = \hat{g}(\text{sh}_G)\). We shall use function extensionality and produce an element \(\hat{g}(x): x \overset{\sim}{\rightarrow} x\) for all \(x: BG\) instead. Note that \(x \overset{\sim}{\rightarrow} x\) is a set, and that connectedness of \(BG\) is not directly applicable here. We will use a technique that has already proven useful in many situations in the book, along the lines of the following sketch:

1. for a given \(x: BG\), if such a \(\hat{g}(x): x \overset{\sim}{\rightarrow} x\) existed, it would produce an element of the type \(T(\hat{g}(x))\) for a carefully chosen type family \(T\),

2. aim to prove \(\text{isContr}((\sum_{u: UG} T(u))\) for any \(x: BG\),

3. this is a proposition, so connectedness of \(BG\) can be applied and only \(\text{isContr}((\sum_{u: UG} T(u))\) needs to be proven,

4. hopefully, \(\sum_{u: UG} T(u)\) reduces to an obvious singleton type.

Here, for any \(x: BG\), we define the type family \(T: (x \overset{\sim}{\rightarrow} x) \rightarrow U\) by

\(T(q) := \prod_{p: \text{sh}_G \overset{\sim}{\rightarrow} x} (p \varphi = qp)\).

And we claim that \(\sum_{q: (x \overset{\sim}{\rightarrow} x)} T(q)\) is contractible for any \(x: BG\). Because this is a proposition, one only need to check that it holds on one point of the connected type \(BG\), say \(x \equiv \text{sh}_G\). We consider the following composition
The definition of the universal cover is reminiscent of the notion of connected component: instead of selecting elements that are merely equal to a fixed element $a$, the universal cover selects elements together with mere witnesses of the equality with $a$. 

Let us say that a pointed type $(A, a)$ is simply connected when both $A$ and $a \Rightarrow a$ are connected types.
Definition 4.12.9. Let $A$ be a type and $a : A$ an element. The universal cover of $A$ at $a$ is the type

$$A_{(a)}^0 := \sum_{x:A} \|a \to x\|_0.$$  

When needed, we will consider $A_{(a)}^0$ as a pointed type, with distinguished point $(a, |\text{refl}|_0)$. Note that when $A$ is a groupoid, then the set truncation is redundant and the universal cover of $A$ at $a$ is then the singleton at $a$. In particular, groupoids have contractible universal covers.

The identity types in $A_{(a)}^0$ can be understood easily once we introduce the following function for elements $x, y, z : A$:

$$\cdot : \|y \to z\|_0 \times \|x \to y\|_0 \to \|x \to z\|_0.$$  

It is defined as follows: given $\chi : \|y \to z\|_0$, we want to define $\chi \cdot \_\_\_$ in the set $\|x \to y\|_0 \to \|x \to z\|_0$, hence we can suppose $\chi \equiv |q|_0$ for some $q : y \to z$; now given $\pi : \|x \to y\|_0$, one want to define $|q|_0 \cdot \pi$ in the set $\|x \to z\|_0$, hence one can suppose $\pi \equiv |p|_0$ for some $p : x \to y$; finally, we define

$$|q|_0 \cdot |p|_0 \equiv |q \cdot p|_0.$$  

Then one proves, by induction on $p : x \to y$, that $\text{trp}_p[^{\|x \to y\|_0}]$ is equal to the function $\alpha \mapsto |p|_0 \cdot \alpha$. In particular, there exists an equivalence from the type of path between two points $(x, a)$ and $(y, b)$ of the universal cover $A_{(a)}^0$ to sum type, analogous to the identification of paths in sum types:

$$(4.12.2)\quad ((x, a) \to (y, b)) \to \sum_{p : x \to y} |p|_0 \cdot \alpha = \beta.$$  

This description allows us to prove the following lemma.

Lemma 4.12.10. Let $A$ be a type and $a : A$ an element. The universal cover $A_{(a)}^0$ is simply connected.

Proof. First, we prove that $A_{(a)}^0$ is connected. It has a point $(a, |\text{refl}|_0)$ and, for every $(x, a) : A_{(a)}^0$, one wants $\|(a, |\text{refl}|_0) \to (x, a)\|$. This is proposition, hence a set, so that one can suppose $\alpha \equiv |p|_0$ for a path $p : a \to x$. Now, the proposition $|p|_0 \cdot |\text{refl}|_0 = |p|_0$ holds. So one can use the inverse of the equivalence of Eq. (4.12.2) to produce a path $(a, |\text{refl}|_0) \to (x, a)$.

Next, we prove that $(a, |\text{refl}|_0) \to (a, |\text{refl}|_0)$ is connected. One uses again the equivalence of Eq. (4.12.2) to produce a composition of equivalences:

$$(a, |\text{refl}|_0) \to (a, |\text{refl}|_0) \to \sum_{p : a \to a} (|p|_0 = |\text{refl}|_0) \to \sum_{p : a \to a} (|p| \equiv |\text{refl}|_0)$$

In other words, $(a, |\text{refl}|_0) \to (a, |\text{refl}|_0)$ is equivalent to the connected component of $\text{refl}_a$ in $a \to a$. In particular, it is connected. \qed

Lemma 4.12.11. Let $A$ be a type pointed at $a : A$. The projection $\text{fst} : A_{(a)}^0 \to A$ is a universal set bundle in the sense of Definition 3.3.10.
Proof. Let \( f : B \to A \) be a pointed set bundle. We need to show that the type of pointed functions \( \varphi : A^0 \to \map{B}{A} \) together with an identification \( q : \text{fst} \to f \varphi \) is contractible. However, such a \( \varphi \) is uniquely determined by the family of functions \( \varphi_x : a \mapsto x \mid f^{-1}(x) \) for \( x : A \). For each \( x : A \), \( f^{-1}(x) \) is a set, so \( \varphi_x \) is uniquely determined by \( \varphi_x \mid \map{\text{refl}}{a} : a \mapsto x \to f^{-1}(x) \).

By induction on \( p : a \mapsto x \to f^{-1}(x) \), we prove that \( \varphi_x \mid (\map{\text{refl}}{a}) : \map{a}{x} \to f^{-1}(x) \). In fact, this pointed type is connected because \( \text{refl} \map{\text{isSet}}{a} \) is a \( 2 \)-type, hence \( \map{a}{x} \to f^{-1}(x) \) is a \( 2 \)-type through univalence.

\[ \begin{aligned} \varphi & : \text{fst} \to f \varphi \\ \map{\varphi}{x} & : a \mapsto x \mid f^{-1}(x) \end{aligned} \]

4.12.12 Abelian groups and simply connected 2-types

We will now give an alternative characterization of the type of abelian groups, more in line with the geometrical intuition we are trying to build in this chapter. Recall that a type \( A \) is called a 2-truncated type, or 2-type for short, when the identity type \( x \mapsto y \) is a groupoid for every \( x, y : A \).

**Theorem 4.12.13.** The type \( \text{AbGroup} \) of abelian groups is equivalent to the type of pointed simply connected 2-types.

Proof. Define the map \( \map{B^2}{\text{AbGroup}}{\mathcal{U}} \), by \( \map{B^2}{G}{\mathcal{U}} \equiv \map{\text{isConn}}{G} \map{\text{isGrpd}}{G} \). Proving that \( B^2 G \) is a 2-type is equivalent to proving the proposition \( \text{isSet}(p \mapsto q) \) for all \( p, q : x \mapsto y \) and all \( x, y : B^2 G \). One can then use connectedness of \( B^2 G \) and restrict to only show that \( p \mapsto q \) is a set for all path \( p, q : (B^2 G, \map{\text{id}_{B^2 G}}{\map{\text{refl}_{B^2 G}}{0}}) \mapsto (B^2 G, \map{\text{id}_{B^2 G}}{\map{\text{refl}_{B^2 G}}{0}}) \). Recall that there is a canonical equivalence of type:

\[ \begin{aligned} (B^2 G, \map{\text{id}_{B^2 G}}{\map{\text{refl}_{B^2 G}}{0}}) & \Rightarrow (B^2 G, \map{\text{id}_{B^2 G}}{\map{\text{refl}_{B^2 G}}{0}}) \\ \sum_{r : B^2 G \Rightarrow B^2 G} & \map{\text{trp}}{r} \map{\text{map}}{\text{id}_{B^2 G}}{\map{\text{refl}_{B^2 G}}{0}} \Rightarrow \map{\text{id}_{B^2 G}}{\map{\text{refl}_{B^2 G}}{0}} \end{aligned} \]

Under that equivalence, \( p \) and \( q \) can be rewritten as \( (p_0, !) \) and \( (q_0, !) \) with \( p_0, q_0 : (B^2 G) \Rightarrow (B^2 G) \) and the elements \( ! \) are proofs of the proposition \( \text{trp}_{p_0} (\map{\text{id}_{B^2 G}}{\map{\text{refl}_{B^2 G}}{0}}) = \map{\text{id}_{B^2 G}}{\map{\text{refl}_{B^2 G}}{0}} \) and \( \text{trp}_{q_0} (\map{\text{id}_{B^2 G}}{\map{\text{refl}_{B^2 G}}{0}}) = \map{\text{id}_{B^2 G}}{\map{\text{refl}_{B^2 G}}{0}} \) respectively. As a consequence, the proposition \( \text{isSet}(p \mapsto q) \) is equivalent to the proposition \( \text{isSet}(p_0 \Rightarrow q_0) \). As part of the definition of the group \( G \), the type \( (B^2 G) \) is a 1-type, hence \( (B^2 G) \Rightarrow (B^2 G) \) is also a 1-type through univalence. This means that \( \text{isSet}(p_0 \Rightarrow q_0) \) holds.

So one gets a map, denoted again \( B^2 \) abusively,

\[ B^2 : \text{AbGroup} \to \mathcal{U}^2 \]

where the codomain \( \mathcal{U}^2 \) is the type of pointed simply connected 2-types, that is

\[ \mathcal{U}^2 \equiv \sum_{(A, a) : \mathcal{U}} (\text{isConn}(A) \times \text{isConn}(a \Rightarrow a) \times \text{isGrpd}(a \Rightarrow a)) \]

We shall now provide an inverse for this map. Given a pointed simply connected 2-type \( (A, a) \), one can construct a group, denoted \( \text{Aut}^2(A, a) \), with classifying type:

\[ \text{BAut}^2(A, a) \equiv (a \Rightarrow a, \text{refl}_a) \]

Indeed, this pointed type is connected because \( (A, a) \) is simply connected, and it is a 1-type because \( A \) is a 2-type. Moreover, \( \text{Aut}^2(A, a) \) is abelian.
To see it, let us use the bare definition of abelian groups (cf. Definition \ref{def:abelian}). We shall then prove that for all elements \( g, h : \text{refl}_A \Rightarrow \text{refl}_A \), the proposition \( gh \sim hg \) holds. This property holds in even more generality and is usually called "Eckmann-Hilton's argument". It goes as follows: for \( x, y, z : A \), for \( p, q : x \rightarrow y \) and \( r, s : y \rightarrow z \) and for \( g : p \rightarrow q \) and \( h : r \rightarrow s \), one prove

\[
\text{(4.12.4)} \quad \text{ap}_{\sim q}(h) \cdot \text{ap}_{\sim r}(g) = \text{ap}_{\sim s}(g) \cdot \text{ap}_{\sim p}(h).
\]

This equality takes place in \( r \cdot p \rightarrow s \cdot q \) and is better represented by the diagram in Fig. 4.5. One prove such a result by induction on \( h \). Indeed,

\[
\begin{array}{c}
\begin{array}{ccc}
\text{x} & \xrightarrow{p} & \text{y} \\
\text{q} & \xrightarrow{r} & \text{z}
\end{array}
\end{array}
\quad \xrightarrow{\sim}
\quad
\begin{array}{c}
\begin{array}{ccc}
\text{x} & \xrightarrow{p} & \text{y} \\
\text{q} & \xrightarrow{r} & \text{z}
\end{array}
\end{array}
\]

when \( h \equiv \text{refl}_A \), then both sides of the equation reduces through path algebra to \( \text{ap}_{\sim}(g) \). Now we are interested in this result when \( x, y, z \) are all equal to \( a \) by definition, and \( p, q, r, s \) are all equal to \( \text{refl}_A \) by definition. In that case, one has that \( \text{ap}_{\sim} \text{refl}_A \) and \( \text{ap}_{\sim} \text{refl}_A \) both act trivially, and the equation becomes: \( h \cdot g \equiv g \cdot h \).

One still has to prove that the function \( \text{Aut}^2 \) is an inverse for \( B^2 \). Given an abelian group \( G \), the proof of Lemma \ref{lem:inverse} gives an equivalence between \( B\text{Aut}^2(G) \) and the connected component of \( \text{refl}_G \) in \( BG \Rightarrow BG \). By definition, this is the classifying type of \( Z(G) \). Being abelian, \( G \) is isomorphic to its center (Lemma \ref{lem:center}), and so it yields an element of \( \text{Aut}^2(G) \) \( \Rightarrow \text{Group} G \). Conversely, take a pointed simply connected 2-type \( (A, a) \). We want to produce a pointed equivalence \( \Phi : (A, a) \Rightarrow \text{B}^2(\text{Aut}^2(A, a)) \). One should first notice that the function

\[
\text{(4.12.5)} \quad \text{ev}_{\sim a} \text{BAut}^2 \left( \text{B}^2(\text{Aut}^2(A, a)) \right) \equiv ((a \sim a) \sim (a \sim a)) (\text{refl}_a) \rightarrow (a \sim a, \text{refl}_a).
\]

that maps a path

\[
(p, !) : (a \sim a, \text{refl}_a) \sim (a \sim a, \text{refl}_a)
\]

to the evaluation \( p(\text{refl}_a) : a \sim a \) is an equivalence, because \( \text{Aut}^2(A, a) \) is an abelian group.

We will now define a pointed map \( \Phi : (A, a) \Rightarrow \text{B}^2(\text{Aut}^2(A, a)) \), and prove subsequently that this is an equivalence. Let \( T : A \rightarrow \mathcal{U} \) be the type family (of sets) define by

\[
T(a') \equiv \sum_{\alpha : ((a \sim a) \sim (a' \sim a')) \sim 0} \prod_{p : a \rightarrow a'} \alpha = |p \cdot -|_0
\]

We claim that \( T(a') \) is contractible for all \( a' : A \). By connectedness of \( A \), it
is equivalent to show that $T(a)$ is contractible. However,

$$T(a) \equiv \sum_{a : \|a \rightarrow a\|} \prod_{p : a \rightarrow a} \alpha = \|p \cdot \|_0$$

\[\cong \sum_{a : \|a \rightarrow a\|} \alpha = \|id_a \rightarrow a\|_0 \]

\[= 1\]

Then, we define $\Phi(a')$ to be the element $(a \sim a', \kappa_{a'}) : \mathcal{U}_{(a \sim a)}^0$ where $\kappa_{a'}$ is the first projection of the center of contraction of $T(a')$. In particular, following the chain of equivalences above, $\Phi(a)$ is defined as $(a \sim a, |\text{refl}_{a \sim a}|_0)$, hence $\Phi(a)$ is trivially pointed by a reflexivity path.

To verify that $\Phi$, thus defined, is an equivalence, one can use connectedness of $B^2(\text{Aut}^2(A, a))$ and only check that $\Phi^{-1}(a \sim a, \text{refl}_{a \sim a}|_0)$ is contractible. However, there is a canonical equivalence of type:

$$\Phi^{-1}(a \sim a, \text{refl}_{a \sim a}|_0) \cong \prod_{a' : A} \prod_{q : (a \sim a') \equiv (a \sim a')} |q|_0 = \kappa_{a'}.$$

So we will show that the type on the right hand-side is contractible. For an element $a' : A$ together with $q : (a \sim a') \equiv (a \sim a')$ such that the proposition $|q|_0 = \kappa_{a'}$ holds, a path between $(a, \text{id}_{a \sim a}, 1)$ and $(a', q, 1)$ consists of a path $p : a \rightarrow a'$ and a path $q : (x \mapsto px) \rightarrow q$. We have a good candidate for $p$, namely $p \equiv q(\text{refl}_a) : a \rightarrow a'$. However we don’t have quite $q$ yet. Consider, for any $a' : A$, the function

$$\text{ev}_{\text{refl}_a}^a : ((a \sim a, |\text{refl}_{a \sim a}|_0) = (a \sim a', \kappa_{a'})) \rightarrow (a \sim a')$$

defined as $(\psi, !) \mapsto \psi(\text{refl}_a)$. Note that $\text{ev}_{\text{refl}_a}^a$ is precisely the equivalence $\text{BAut}^2(B^2(\text{Aut}^2(A, a)) \equiv (a = a)$ described in Eq. (4.12.5). Hence, by connectedness of $A$, one gets that the proposition $\text{Equiv}(\text{ev}_{\text{refl}_a}^a)$ holds for all $a' : A$. In particular, because the propositions $|q|_0 \equiv \kappa_{a'}$ and $|p \cdot \|_0 \equiv \kappa_{a'}$ holds, one gets elements $(q, 1)$ and $(x \mapsto px, 1)$ in the domain of $\text{ev}_{\text{refl}_a}^a$. Their images $\text{ev}_{\text{refl}_a}^a(q, 1)$ and $\text{ev}_{\text{refl}_a}^a(x \mapsto px, 1)$ are both identifiable with $p$. By composition, we obtain a path $(x \mapsto px, 1) \equiv (q, 1)$ in the domain. The first component provide the path $q : (x \mapsto px) \rightarrow q$ that we wanted. \hfill $\Box$

### 4.12.14 Higher deloopings

The function $B^2$ defined in the proof of Theorem 4.12.13 provides a delooping of $BG$ whenever $G$ is abelian. That is, there is an identification $\Omega B^2 G \Rightarrow BG$. A systematic way of obtaining such deloopings has been developed by David Wärn\textsuperscript{38}, that can be applied here to give an alternative definition of $B^2 G$, and to obtain further deloopings of it.

**Definition 4.12.15** (Wärn). Given a pointed type $X$, the type of $X$-torsors is

$$TX \equiv \sum_{Y : \text{ti}} \|Y\| \times \left( \prod_{y : Y} (Y, y) \rightarrow X \right).$$

The type of pointed $X$-torsors is $TX_* : \sum_{t : TX} \text{fst} t$. \hfill $\diamond$

The usefulness of these definitions in the context of deloopings comes from the following proposition.

Lemma 4.12.16 (Wärn). Let $X$ be a pointed type. If $TX$, is contractible, then for any pointed $X$-torsors $(t, y)$, the pointed type $(TX, t)$ is a delooping of $X$.

Proof. Suppose $(t, y)$ is a center of contraction for $TX$. By contracting away (Lemma 2.9.10) in two different ways, we obtained a composition of equivalences:

$$ (t \xrightarrow{0} t) \xrightarrow{\sum_{u : TX}} \text{fst } u \times (t \xrightarrow{0} u) \xrightarrow{\text{fst}} t $$

that maps $\text{refl}_{t}$ to $y$. In other words, this equivalence, trivially pointed, presents $(TX, t)$ as a delooping of $(\text{fst } t, y)$. Moreover, the $X$-torsor $t$ comes by definition with an identification $(t, y) \xrightarrow{\cdot_{t}} X$. So in the end, we have an equivalence $(TX, t) \xrightarrow{\cdot_{t}} X$.

Exercise 4.12.17. Recall that a section (see Definition 2.17.1 and its accompanying footnote) of a function $f : A \to B$ is a function $s : B \to A$ together with an identification $f \circ s \xrightarrow{\cdot} \text{id}\_B$. Construct an equivalence from the type $\text{sec } f$ of sections of $f$ to the type $\prod_{b : B} \sum_{a : A} b \xrightarrow{\cdot} f(a)$.

Consider the evaluation function $\text{ev}_{X, Y} : (X. \xrightarrow{0} Y) \to Y$ (defined by path-induction, sending $\text{refl}_X$ to the distinguished point of $X$). In other words, the function $\text{ev}_{X, Y}$ takes an identification of $X$ with $Y$ and returns the point in $Y$ corresponding to the distinguished point of $X$ under this identification. Applying Exercise 4.12.17 to $\text{ev}_{X, Y}$ we get an equivalence of type

$$ TX \xrightarrow{\cdot} \sum_{Y : U} \|Y\| \times \text{sec}(\text{ev}_{X, Y}). $$

This alternative description of the type of $X$-torsors is the key ingredient to compare Wärn’s delooping of the classifying type of an abelian group with our.

Lemma 4.12.18. For any abelian group $G$, the type $T(BG)$ can be identified with $B^2G$.

Proof. Let $G$ be an abelian group. We first construct, for each type $Y$, a function $f_Y : \|Y\| \times \text{sec}(\text{ev}_{BG, Y}) \to \|BG\_G\_G \xrightarrow{=_{BG}} Y\|_0$, and then prove that $f_Y$ is an equivalence. Given a type $Y$ and an element $(l, s) : \|Y\| \times \text{sec}(\text{ev}_{X, Y})$, we can easily prove that $Y$ is connected: being connected is a proposition, so we can assume that we have an actual $y : Y$ and then $s(y) : BG_\_G \xrightarrow{=_{BG}} Y$ proves that $Y$ is as connected as $BG_\_G$ is. Consequently $s$ must send $Y$ into one of the connected components of $BG_\_G \xrightarrow{=_{BG}} Y$, that we choose to be $f_Y(l, s)$. With this definition, the fiber of $f_Y$ at any given $c : \|BG\_G \xrightarrow{=_{BG}} Y\|_0$ can be identified with the type of sections $s$ of $\text{ev}_{BG, Y}$ with values in $c$. However, for any $Z$ and $p : BG_\_G \xrightarrow{=_{BG}} Z$ the restriction of the evaluation $\text{ev}_{BG, Z} \upharpoonright_p : (BG_\_G \xrightarrow{=_{BG}} Z)\_p \to Z$ is an equivalence: indeed, by induction, we only have to show it for $p = \text{refl}_{BG_\_G}$, in which case $\text{ev}_{BG, BG_\_G} \upharpoonright_{\text{refl}_{BG_\_G}}$ is exactly the map $BzG$ defined in Section 4.12.1, which is an equivalence since $G$ is abelian by Lemma 4.12.6. Thus, given any $p$, the fiber of $f_Y$ at $\|p\|_0$ is contractible. Being contractible is a proposition, hence a set, so it follows that the fiber of $f_Y$ at any $c : \|BG\_G \xrightarrow{=_{BG}} Y\|_0$ is contractible. In other words, $f_Y$ is an equivalence, as announced. We have thus a chain of equivalences: 39

50 Notice that the construction of an equivalence $TX \xrightarrow{\cdot_{X, X}}$, that we carried for $X = BG$ relies only on $X$, being connected and $\text{ev}_{X, X} \upharpoonright_{\text{refl}_{X}}$ being an equivalence. Such types $X$ are called central and are studied in details by Buchholtz et al. 40.

Notice that where Wärn's method shines, compared to our, is in producing further delooping $B^nG$ for $n \geq 3$.

### 4.13 $G$-sets vs $\text{abs}(G)$-sets

Given a group $G$ it should by now come as no surprise that the type of $G$-sets is equivalent to the type of $\text{abs}(G)$-sets. According to Lemma 4.10.1

$$\text{abs} : \text{Hom}(G, \Sigma_X) \to \text{Hom}^{\text{abs}}(\text{abs}(G), \text{abs}(\Sigma_X))$$

is an equivalence, where the group $\Sigma_X$ (as a pointed connected groupoid) is the component of the groupoid $\text{Set}$, pointed at $X$. The component information is moot since we’re talking about pointed maps from $BG$. And we see that $\text{Hom}(G, \Sigma_X)$ is equivalent to $\text{Hom}_{F : BG \to \text{Set}}(X = F(\text{sh}_G))$.

Finally,

$$\text{pr} : \sum_{X : \text{F : BG} \to \text{Set}} (X = F(\text{sh}_G)) \xrightarrow{\sim} (BG, \to \text{Set}), \quad \text{pr} (X, F, p) \equiv F$$

is an equivalence (since $\sum_X (X = F(\text{sh}_G))$ is contractible). Backtracking these equivalences we see that we have established

**Lemma 4.13.1.** Let $G$ be a group. Then the map

$$\text{ev}_{\text{sh}} : G\text{-Set} \to \text{Set}^{\text{abs}(G)}, \quad \text{ev}_{\text{sh}} (X) \equiv (X(\text{sh}_G), \vartheta_X)$$

is an equivalence, where the homomorphism $\vartheta_X : \text{Hom}^{\text{abs}}(\text{abs}(G), \text{abs}(\Sigma_{\text{sh}}(G)))$ is given by transport $X : UG \equiv (\text{sh}_G = \text{sh}_C) \to (X(\text{sh}_G) = X(\text{sh}_C))$.

If $X$ is a $G$ set, $g : UG$ and $x : X(\text{sh}_G)$, we seek forgiveness for writing $\Sigma : X(\text{sh}_G)$ instead of cast $(\vartheta_X (g)) (x)$.

**Example 4.13.2.** Let $H$ and $G$ be groups. Recall that the set of homomorphisms from $H$ to $G$ is a $G$-set in a natural way:

$$\text{Hom}(H, G) : BG \to \text{Set}, \quad \text{Hom}(H, G)(g) \equiv \sum_{F : BH \to BG} (y = F(\text{sh}_H)).$$

What abstract $\text{abs}(G)$-set does this correspond to? In particular, under the equivalence $\text{abs} : \text{Hom}(H, G) \to \text{Hom}^{\text{abs}}(\text{abs}(H), \text{abs}(G))$, what is the corresponding action of $\text{abs}(G)$ on the abstract homomorphisms?

The answer is that $g : UG$ acts on $\text{Hom}^{\text{abs}}(\text{abs}(H), \text{abs}(G))$ by postcomposing with conjugation $\text{conj}^g$ by $g$ as defined in Example 4.4.25.

Let us spell this out in some detail: If $(F, p) : \text{Hom}(H, G)(\text{sh}_G) \equiv \sum_{F : BH \to BG} (\text{sh}_G = F(\text{sh}_H))$ and $g : UG$, then $g : (F, p) \equiv (F, p \cdot g^{-1})$. If we show that the action of $g$ sends $\text{abs}(F, p)$ to $\text{conj}^g \circ \text{abs}(F, p)$ we are done.

Recall that $\text{abs}(F, p)$ consists of the composite

$$\text{abs} \xrightarrow{F} (F(\text{sh}_H) = F(\text{sh}_C)) \xrightarrow{F^{-1}\cdot p} UG,$$

(i.e., $\text{abs}(F, p)$ applied to $q : UH$ is $p^{-1}F^{-1}(q) p$ together with the proof that this is an abstract group homomorphism. We see that $\text{abs}(F, p \cdot g^{-1})$ is given by conjugation: $q \mapsto (p \cdot g^{-1})^{-1}F^{-1}(q) (p \cdot g^{-1}) = g (p^{-1}F^{-1}(q) p) g^{-1}$, or in other words $\text{conj}^g \circ \text{abs}(F, p)$.

\[\square\]

Recall from Definition 4.9.1 that the type of $\text{abs}(G)$-set is

$$\text{Set}_{\text{abs}(G)} \equiv \sum_{X : \text{Set}} \text{Hom}_{\text{abs}}(\text{abs}(G), \text{abs}(\Sigma_X)).$$
For reference we list the conclusion of this example as a lemma:

**Lemma 4.13.3.** If $H$ and $G$ are groups, then the equivalence of Lemma 4.13.1 sends the $G$-set $\text{Hom}(H, G)$ to the $\text{abs}(G)$-set $\text{Hom}^{\text{abs}}(\text{abs}(H), \text{abs}(G))$ with action given by postcomposing with conjugation by elements of $\text{abs}(G)$.

If $f : \text{Hom}(G, G')$ is a homomorphism, then precomposition with $Bf : BG \to BG'$ defines a map

$$f^* : (G'-\text{Set}) \to (G-\text{Set}).$$

We will have the occasion to use the following result which essentially says that if $f : \text{Hom}(G, G')$ is an epimorphism, then $f^*$ embeds the type of $G'$-sets as some of the components of the type of $G$-sets.

**Lemma 4.13.4.** Let $G$ and $G'$ be groups and let $f : \text{Hom}(G, G')$ be an epimorphism. Then the map $f^* : (G'-\text{Set}) \to (G-\text{Set})$ (induced by precomposition with $Bf : BG \to BG'$) is “fully faithful” in the sense that if $X, Y$ are $G'$-sets, then

$$f^* : (X = Y) \to (f^* X = f^* Y)$$

is an equivalence.

**Proof.** Evaluation at $sh_C$ yields an injective map

$$ev_{sh_C} : (f^* X = f^* Y) \to (X(f(sh_C)) = Y(f(sh_C)))$$

and the composite

$$ev_{sh_C} f^* = ev_{f(sh_C)} : (X = Y) \to (X(f(sh_C)) = Y(f(sh_C)))$$

is the likewise injective, so $f^* : (X = Y) \to (f^* X = f^* Y)$ is injective.

For surjectivity, let $F : f^* X = f^* Y$ and write, for typographical convenience, $a : X(f(sh_C)) = Y(f(sh_C))$ for $ev_{sh_C} F' := F'_{sh_C}$. By the equivalence between $G$-sets and $\text{abs}(G)$-sets, $F'$ is uniquely pinned down by $a$ and the requirement that for all $g' = f(g)$ with $g : UG$ the diagram

$$\begin{array}{ccc}
X(f(sh_C)) & \xrightarrow{X(g')} & X(f(sh_C)) \\
\downarrow & & \downarrow \\
Y(f(sh_C)) & \xrightarrow{Y(g')} & Y(f(sh_C))
\end{array}$$

commutes. Likewise, (using transport along the identity $p_f : sh_{G'} = f(sh_C)$) an $F : X = Y$ in the preimage of $a$ is pinned down by the commutativity of the same diagram, but with $g' : f(sh_C) = f(sh_C)$ arbitrary (an a priori more severe requirement, again reflecting injectivity). However, when $f : UG \to UG'$ is surjective these requirements coincide, showing that $f^*$ is an equivalence.

\[\square\]

### 4.14 Semidirect products

**just moved without proofreading BID 211116**

In this section we describe a generalization of the product of two group, called the semidirect product, which can be constructed from an action of a group on a group. Like the product, it consists of pairs, both at the level of concrete groups and of abstract groups, as we shall see.
We start with some preliminaries on paths between pairs. Lemma 2.10.3 above takes a simpler form when \( y \) and \( y' \) are values of a family \( x \mapsto f(x) \) of elements of the family \( x \mapsto Y(x) \), as the following lemma shows.

**Lemma 4.14.1.** Suppose we are given a type \( X \) and a family of types \( Y(x) \) parametrized by the elements \( x \) of \( X \). Suppose we are also given a function \( f : \prod_{x : X} Y(x) \). For any elements \( x \) and \( x' \) of \( X \), there is an equivalence of type

\[
((x, f(x)) = (x', f(x'))) \simeq (x = x') \times (f(x) = f(x)),
\]

where the identity type on the left side is between elements of \( \sum_{x : X} Y(x) \).

**Proof.** By Lemma 2.10.3 and by composition of equivalences, it suffices to establish an equivalence of type

\[
\left( \sum_{p : x = y'} f(x) \simeq \sum_{p : x = y'} f(x') \right) \simeq \left( \sum_{p : x = y'} (f(x) = f(x)) \right).
\]

Rewriting the right hand side as a sum over a constant family, it suffices to find an equivalence of type

\[
\left( \sum_{p : x = x'} f(x) \simeq f(x') \right) \simeq \left( \sum_{p : x = x'} (f(x) = f(x)) \right).
\]

By Lemma 2.10.3 it suffices to establish an equivalence of type

\[
\left( f(x) \simeq f(x') \right) \simeq (f(x) = f(x))
\]

for each \( p : x = x' \). By induction on \( x' \) and \( p \) we reduce to the case where \( x' = x \) and \( p \) is \( \text{refl}_x \), and it suffices to establish an equivalence of type

\[
\left( f(x) \simeq f(x) \right) \simeq (f(x) = f(x)).
\]

Now the two sides are equal by definition, so the identity equivalence provides what we need. \( \square \)

The lemma above shows how to rewrite certain paths between pairs as paths of pairs. Now we wish to establish the formula for composition of paths, rewritten in terms of pairs of paths, but first we introduce a convenient definition for the transport of loops in \( Y(x) \) along paths in \( X \).

**Definition 4.14.2.** Suppose we are given a type \( X \) and a family of types \( Y(x) \) parametrized by the elements \( x \) of \( X \). Suppose we are also given a function \( f : \prod_{x : X} Y(x) \). For any elements \( x \) and \( x' \) of \( X \) and any identity \( p : x = x' \), define a function \( (f(x') = f(x')) \mapsto (f(x) = f(x)) \), to be denoted by \( q' \mapsto q'' \), by induction on \( p \) and \( x' \), reducing to the case where \( x' = x \) and \( p \) is \( \text{refl}_x \), allowing us to set \( q'' \equiv q' \).

We turn now to associativity for the operation just defined.

**Lemma 4.14.3.** Suppose we are given a type \( X \) and a family of types \( Y(x) \) parametrized by the elements \( x \) of \( X \). Suppose we are also given a function \( f : \prod_{x : X} Y(x) \). For any elements \( x, x', \) and \( x'' \) of \( X \), for any identities \( p : x = x' \) and \( p' : x' = x'' \), and for any \( q : f x'' = f x'' \), there is an identification of type \( (q'' \mapsto q'') \equiv q' \).
Proof. By induction on $p$ and $p'$, it suffices to show that $(q_{\text{refl}})^{\text{refl}} = q_{\text{refl},\text{refl}}$, in which both sides are equal to $q$ by definition. \(\square\)

Observe that the operation depends on $f$, but $f$ is not included as part of the notation.

Lemma 4.14.4. Suppose we are given a type $X$ and a family of types $Y(x)$ parametrized by the elements $x$ of $X$. Suppose we are also given a function $f : \prod_{x : X} Y(x)$. For any elements $x$, $x'$, and $x''$ of $X$, and for any two identities $e : (x, f(x)) = (x', f(x'))$ and $e' : (x', f(x')) = (x'', f(x''))$, if $e$ corresponds to the pair $(p, q)$ with $p : x = x'$ and $q : f x = f x'$ under the equivalence of Lemma 4.14.1, and $e'$ corresponds to the pair $(p', q')$ with $p' : x' = x''$ and $q' : f x' = f x''$, then $e' \cdot e$ corresponds to the pair $(p' \cdot p, (q' \cdot q))$.

Proof. By induction on $p$ and $p'$ we reduce to the case where $x'$ and $x''$ are $x$ and $p$ and $p'$ are $\text{refl}$. It now suffices to show that $e' \cdot e$ corresponds to the pair $(\text{refl}, q' \cdot q)$. Applying the definition of the map $\Phi$ in the proof of Lemma 2.10.3 to our three pairs, we see that it suffices to show that $(\text{ap}_{p}(\text{refl}_{x})(q')) \cdot (\text{ap}_{q}(\text{refl}_{y})(q)) = \text{ap}_{q'}(\text{refl}_{y})(q' \cdot q)$, with $g$, as there, being the function $g(x)(y) \equiv (x, y)$. By Definition 2.7.8 it suffices to show that $(\text{ap}_{g(x)} q') \cdot (\text{ap}_{g(y)} q) = \text{ap}_{g(x)}(q' \cdot q)$, which follows from compatibility of $\text{ap}_{g(x)}$ with composition, as in Construction 2.6.2. \(\square\)

The lemma above will be applied mostly in the case where $x'$ and $x''$ are $x$, but if it had been stated only for that case, we would not have been able to argue by induction on $p$ and $p'$.

Definition 4.14.5. Given a group $G$ and an action $\tilde{H} : BG \to \text{Group}$ on a group $H \equiv \tilde{H}(\text{sh}_G)$, we define a group called the semidirect product as follows.

$$G \rtimes \tilde{H} \equiv \bigodot_{t : BG} B\tilde{H}(t)$$

Here the basepoint of the sum is taken to be the point $(\text{sh}_G, \text{sh}_H)$. (We deduce from Lemma 2.15.5, Item (4), that $\sum_{t : BG} B\tilde{H}(t)$ is a groupoid. See Exercise 2.16.12 for a proof that $\sum_{t : BG} B\tilde{H}(t)$ is connected.) \(\checkmark\)

Observe that if the action of $G$ on $H$ is trivial, then $\tilde{H}(t) \equiv H$ for all $t$ and $G \rtimes \tilde{H} \equiv G \times H$.

Projection onto the first factor gives a homomorphism $p : \equiv \bigodot_{t : BG} \text{fst} : G \ltimes \tilde{H} \to G$. Moreover, there is a homomorphism $s : G \to G \ltimes \tilde{H}$ defined by $s : \equiv \bigodot_{t : BG} \left( t \mapsto (t, \text{sh}_H(t)) \right)$, for $t : BG$. The two maps are homomorphisms because they are made from basepoint-preserving maps. The map $s$ is a section of $p$ in the sense the $p \circ s = \text{id}_G$. There is also a homomorphism $j : H \to G \ltimes \tilde{H}$ defined by $j : \equiv \bigodot_{u : BH} (u \mapsto (\text{sh}_G, u))$, for $u : BH$.

Lemma 4.14.6. The homomorphism $j$ above is a monomorphism, and it gives the same (normal) subgroup of $G \ltimes \tilde{H}$ as the kernel ker $p$ of $p$.

Proof. See 5.3.2 for the definition of kernel. According to Lemma 2.25.1, the map $BH \to (Bp)^{-1}(\text{sh}_G)$ defined by $u \mapsto ((\text{sh}_G, u), \text{refl}_{\text{sh}_G})$ is an equivalence. This establishes that the fiber $(Bp)^{-1}(\text{sh}_G)$ is connected and thus serves as the classifying type of ker $p$. Pointing out that the
composite map \( H \xrightarrow{\sim} \ker p \to G \times H \) is \( j \) and using univalence to promote the equivalence to an identity gives the result.

Our next goal is to present the explicit formula for the multiplication operation in \( UG \times H \). First we apply Lemma 4.14.1 to get a bijection \( UG \times H = UG \times UH \). Now use that to transport the multiplication operation of the group \( UG \times H \) to the set \( UG \times UH \). Now Lemma 4.14.4 tells us the formula for that transported operation is given as follows.

\[
(p', q') \cdot (p, q) = (p' \cdot p, (q''p) \cdot q)
\]

In a traditional algebra course dealing with abstract groups, this formula is used as the definition of the multiplication operation on the set \( UG \times UH \), but then one must prove that the operation satisfies the properties of Definition 4.3.1. The advantage of our approach is that the formula emerges from the underlying logic that governs how composition of paths works.

### 4.15 The pullback

Given two functions \( f : B \to D \) and \( g : C \to D \) with common target, the “pullback” which we will now define should be thought about as the type of all pairs of elements \((b, c) : B \times C\) so that \( f(b) = g(c)\). This construction is important in many situations also beyond group theory.

**Definition 4.15.1.** Let \( B, C, D\) be types and let \( f : B \to D \) and \( g : C \to D \) be two maps. The pullback of \( f \) and \( g \) is the type

\[
\prod(f, g) \equiv \sum_{(b, c) : B \times C} (f(b) = D g(c))
\]

together with the two projections \( \text{pr}_B : \prod(f, g) \to B \) and \( \text{pr}_C : \prod(f, g) \to C \) sending \((b, c, p) : \prod(f, g)\) to \( b : B \) or \( c : C \). If \( f \) and \( g \) are clear from the context, we may write \( B \times_D C \) instead of \( \prod(f, g) \) and summarize the situation by the diagram

\[
\begin{array}{ccc}
B \times_D C & \xrightarrow{\text{pr}_C} & C \\
\downarrow^{\text{pr}_B} & & \downarrow^{g} \\
B & \xrightarrow{f} & D.
\end{array}
\]

**Exercise 4.15.2.** Let \( f : B \to D \) and \( g : C \to D \) be two maps with common target. If \( A \) is a type show that

\[
(A \to B) \times_{(A \to D)} (A \to C) \to (A \to B \times_D C)
\]

\[
(\beta, \gamma, p : f \beta = g \gamma) \mapsto (a \mapsto (f(a), g(a), p(a) : f \beta(a) = g \gamma(a)))
\]

is an equivalence.

In view of Exercise 4.15.2 we will say that we have a pullback diagram

\[
\begin{array}{ccc}
A & \xrightarrow{f} & C \\
\downarrow^{f'} & & \downarrow^{g'} \\
B & \xrightarrow{f} & D
\end{array}
\]

to indicate that we have an element in \((A \to B) \times_{(A \to D)} (A \to C)\) such that the resulting map \( A \to B \times_D C \) is an equivalence.
Example 4.15.3. If \( g : \mathbb{1} \to D \) has value \( d : D \) and \( f : B \to D \) is any map, then \( \prod_{\mathbb{1}} (f, g) \equiv B \times_D \mathbb{1} \) is equivalent to the preimage \( f^{-1}(d) \equiv \sum_{b : B} d = f(b) \).

Example 4.15.4. Much group theory is hidden in the pullback. For instance, the greatest common divisor \( \gcd(a, b) \) of \( a, b : \mathbb{N} \) is another name for the number of components you get if you pull back the \( a \)-fold and the \( b \)-fold set bundles of the circle: we have a pullback

\[
\begin{array}{c}
S^1 \times B_{\gcd(a, b)} \\
\downarrow \\
S^1 \\
\downarrow (-)^a \\
S^1
\end{array}
\]

(where \( C_n \) was the cyclic group of order \( n \)). To get a geometric idea, think of the circle as the unit circle in the complex numbers so that the \( a \)-fold set bundle is simply taking the \( a \)-fold power. With this setup, the pullback should consist of pairs \( (z_1, z_2) \) of unit length complex numbers with the property that \( z_1^a = z_2^b \). Let \( a = a' \gcd(a, b) \) and \( b = b' \gcd(a, b) \). Taking an arbitrary unit length complex number \( z \), then the pair \( (z^{a'}, z^{b'}) \) is in the pullback (since \( a' b = a b' \)). But so is \( (\zeta z^{a'}, z^{a'}) \), where \( \zeta \) is any \( \gcd(a, b)^{th} \) root of unity. Each of the \( \gcd(a, b) \)-choices of \( \zeta \) contributes in this way to a component of the pullback. In more detail: identifying the cyclic group \( C_{\gcd(a, b)} \) of order \( \gcd(a, b) \) with the group of \( \mathbb{g}^{th} \) roots of unity, the top horizontal map \( S^1 \times C_{\gcd(a, b)} \to S^1 \) sends \( (z, \zeta) \) to \( z^{a'} \) and the left vertical map sends \( (z, \zeta) \) to the product \( \zeta z^{b'} \).

Also the least common multiple \( \text{lcm}(a, b) = a' b \) is hidden in the pullback; in the present example it is demonstrated that the map(s) across the diagram makes each component of the pullback a copy of the \( \text{lcm}(a, b) \)-fold set bundle.

Definition 4.15.5. Let \( S \) be a set and consider two subsets \( A \) and \( B \) of \( S \) given by two families of propositions (for \( s : S \)) \( P(s) \) and \( Q(s) \). The intersection \( A \cap B \) of the two subsets is given by the family of propositions \( P(s) \times Q(s) \). The union \( A \cup B \) is given by the set family of propositions \( A(s) + B(s) \).

Exercise 4.15.6. Given two subsets \( A, B \) of a set \( S \), prove that

1. The pullback \( A \times_S B \) maps by an equivalence to the intersection \( A \cap B \),
2. If \( S \) is finite, then the sum of the cardinalities of \( A \) and \( B \) is equal to the sum of the cardinalities of \( A \cup B \) and \( A \cap B \).

Definition 4.15.7. Let \( f : \text{Hom}(H, G) \) and \( f' : \text{Hom}(H', G) \) be two homomorphisms with common target. The pullback \( H \times_G H' \) is the group obtained as the (pointed) component of

\[
\text{pt}_{H \times_G H'} := (\text{sh}_H, \text{pt}_{H'}, f' \circ f^{-1})
\]

of the pullback \( B H \times_{BG} B H' \) (where \( p_f : \text{sh}_G = f(\text{sh}_H) \) is the name we chose for the data displaying \( f \) as a pointed map, so that \( p_f \circ f^{-1} : f(\text{sh}_H) = f'(\text{pt}_{H'}) \)).

If \((H, f, !)\) and \((H', f', !)\) are monomorphisms into \( G \), then the pullback is called the intersection and if the context is clear denoted simply \( H \cap H' \).
Example 4.15.8. If \( a, b : \mathbb{N} \) are natural number with least common multiple \( L \), then \( LZ \) is the intersection \( aZ \cap bZ \) of the subgroups \( aZ \) and \( bZ \) of \( Z \).

Exercise 4.15.9. Prove that if \( f : \text{Hom}(H, G) \) and \( f' : \text{Hom}(H', G) \) are homomorphisms, then the pointed version of Exercise 4.15.2 induces an equivalence

\[
\text{Hom}(K, H) \times_{\text{Hom}(K, G)} \text{Hom}(K, H') \simeq \text{Hom}(K, H \times_G H')
\]

for all groups \( K \) and an equivalence

\[
\text{UH} \times_{\text{UG}} \text{UH}' \simeq (\text{sh}_{H \times_G H'} = \text{sh}_{H \times_G H'}).^{43}
\]

Elevate the last equivalence to a statement about abstract groups.

Remark 4.15.10. The pullback is an example of when a construction of types not preserving connectivity can be used profitably also for groups. We get the pullback of groups by restricting to a pointed component, but also the other components have group theoretic importance. We will return to this when discussing subgroups.

4.16 Sums of groups

We have seen how the group of integers \( \mathbb{Z} = (S^1, \cdot) \) synthesizes the notion of one symmetry with no relations: every symmetry in the circle is of the form \( \bigcirc^n \) for some unique \( n \). Also, given any group \( G = \text{Aut}_A(a) \), the set \( a = a \) of symmetries of \( a \) corresponds to the set of homomorphisms \( Z \to G \), i.e., to pointed functions \( (S^1, \cdot) \to (A, a) \) by evaluation at \( \bigcirc \). What happens if we want to study more than one symmetry at the time?

For instance, is there a group \( Z \vee Z \) so that for any group \( G = \text{Aut}_A(a) \) a homomorphism \( Z \vee Z \to G \) corresponds to two symmetries of \( a \)? At the very least, \( Z \vee Z \) itself would have to have two symmetries and these two can’t have any relation, since in a general group \( G = \text{Aut}_A(a) \) there is a priori no telling what the relation between the symmetries of \( a \) might be. Now, one symmetry is given by a pointed function \( (S^1, \cdot) \to (A, a) \) and so a pair of symmetries is given by a function \( f : S^1 + S^1 \to A \) with the property that \( f \) sends each of the base points of the circles to \( a \). But \( S^1 + S^1 \) is not connected, and so not a group. To fix this we take the clue from the requirement that both the base points were to be sent to a common base point and define \( S^1 \vee S^1 \) to be what we get from \( S^1 + S^1 \) when we insert an identity between the two basepoints.

The amazing thing is that this works – an enormous simplification of the classical construction of the “free products” or “amalgamated sum” of groups. We need to show that the “wedge” \( S^1 \vee S^1 \) is indeed a group, and this proof simultaneously unpacks the classical description.

We start by giving a definition of the wedge construction which is important for pointed types in general and then prove that the wedge of two groups is a group whose symmetries are arbitrary “words” in the original symmetries.

Definition 4.16.1. Let \( (A_1, a_1) \) and \( (A_2, a_2) \) be pointed types. The wedge is the pointed type \( (A_1 \vee A_2, a_{12}) \) given as a higher inductive type by

(1) functions \( i_1 : A_1 \to A_1 \vee A_2 \) and \( i_2 : A_2 \to A_1 \vee A_2 \)

S^1 \vee S^1 if formed from S^1 + S^1 by inserting an identity

Identify!
(2) an identity \( g : i_1 a_1 = i_2 a_2 \).

We point this type at \( a_{12} \equiv i_1 a_1 \). The function
\[
i_2^g : (a_2 \equiv a_1 a_2) \rightarrow (a_{12} = A_1 \vee A_2 a_{12})
\]
is defined by \( i_2^g(p) \equiv g^{-1} i_2(p) g \), whereas (for notational consistency only) we set \( i_2^\ast \equiv i_1 : (a_1 = A_1 \equiv a_1) \rightarrow (a_{12} = A_1 \vee A_2 a_{12}) \). Simplifying by writing \( i : A_1 + A_2 \rightarrow A_1 \vee A_2 \) for the function given by \( i_1 \) and \( i_2 \) (with basepoints systematically left out of the notation), the induction principle is
\[
\prod_{C : (A_1 \vee A_2) \rightarrow U} \sum_{s : \prod_{i_1, A_1 + A_2} C(i)} ((s(a_1) = C(g^{-1}) s(a_2)) \rightarrow \prod_{x : (A_1 \vee A_2)} C(x)).
\]

Unraveling the induction principle we see that if \( B \) is a pointed type, then a pointed function \( f : A_1 \vee A_2 \rightarrow B \) is given by providing pointed functions \( f_1 : A_1 \rightarrow B \) and \( f_2 : A_2 \rightarrow B \) – the identity \( f_1(a_1) = f_2(a_2) \) which seems to be missing is provided by the requirement of the functions being pointed. For the record

**Lemma 4.16.2.** If \( B \) is a pointed type, then the function
\[
i^* : (A_1 \vee A_2 \rightarrow B) \rightarrow (A_1 \rightarrow B) \times (A_2 \rightarrow B), \quad i^* = (f i_1, f i_2)
\]
is an equivalence.

To the right you see a picture of \( i_2^g(p) \): it is the symmetry of the base point \( a_{12} \equiv i_1 a_1 \) you get by first moving to \( i_2 a_2 \) with \( g \), then travel around with \( p \) (\( i_2 p \), really) and finally go home to the basepoint with the inverse of \( g \).

**Definition 4.16.3.** If \( G_1 = \text{Aut}_{A_1}(a_1) \) and \( G_2 = \text{Aut}_{A_2}(a_2) \) are groups, then their sum is defined as
\[
G_1 \vee G_2 : \equiv \text{Aut}_{A_1 \vee A_2}(a_{12}).
\]
The homomorphisms \( i_1 : G_1 \rightarrow G_1 \vee G_2 \) and \( i_2 : G_2 \rightarrow G_1 \vee G_2 \) induced from the structure maps \( i_1 : A_1 \rightarrow A_1 \vee A_2 \) and \( i_2 : A_2 \rightarrow A_1 \vee A_2 \) are also referred to as structure maps.

**Lemma 4.16.4.** If \( G_1, G_2 \) and \( G \) are groups, then the function
\[
\text{Hom}(G_1 \vee G_2, G) \rightarrow \text{Hom}(G_1, G) \times \text{Hom}(G_2, G)
\]
given by restriction along the structure maps is an equivalence.

**Proof.** This is a special case of Lemma 4.16.2. \( \square \)

Specializing further, we return to our initial motivation and see that mapping out of a wedge of two circles exactly captures the information of two independent symmetries:

**Corollary 4.16.5.** If \( G \) is a group, then the functions
\[
\text{Hom}(\mathbb{Z} \vee \mathbb{Z}, G) \rightarrow \text{Hom}(\mathbb{Z}, G) \times \text{Hom}(\mathbb{Z}, G) \cong \text{UG} \times \text{UG}
\]
is an equivalence.
Exercise 4.16.6. This leads to the following characterization of abelian groups formulated purely in terms of pointed connected groupoids (with no direct reference to identity types). A group $G$ is abelian if and only if the canonical map

$$\text{fold} : BG \vee BG \rightarrow BG$$

(given via Lemma 4.16.4 by $\text{id}_G : G \rightarrow G$) extends over the inclusion

$$i : BG \vee BG \rightarrow BG \times BG$$

(given by the inclusions $\text{in}_1, \text{in}_2 : G \rightarrow G \times G$).

As a cute aside, one can see that the required map $BG \times BG \rightarrow BG$ actually doesn’t need to be pointed: factoring fold $BG \vee BG \rightarrow BG$ over $i : BG \vee BG \rightarrow BG \times BG$ – even in an unpointed way – kills all “commutators” $ghg^{-1}h^{-1} : U(G \vee G)$. (Is this still a proposition, or do we need to truncate?)

We end the section by proving that wedges of decidable groups are decidable groups and that they can be given the classical description in terms of words.

**Lemma 4.16.7.** Let $G_1 \equiv \text{Aut}_{A_1}(a_1)$ and $G_2 \equiv \text{Aut}_{A_2}(a_2)$ be decidable groups, then the wedge sum $G_1 \vee G_2 \equiv \text{Aut}_{A_1 \vee A_2}(a_{12})$ is a decidable group.

Let $C_1$ be the set of strings $(p_0, n, p_1, \ldots, p_n)$ with $n : \mathbb{N}$ and, for $0 \leq j \leq n$

- $p_j : UG_1$ for even $j$
- $p_j : UG_2$ for odd $j$ and
- $p_j$ is not reflexivity for $j$ positive

(the last requirement makes sense and is a proposition since our groups are decidable).

Then the function given by composition in $UG_{12} \equiv (a_{12} = a_{12})$

$$\beta : C_1 \rightarrow UG_{12}, \quad \beta(p_0, n, p_1, \ldots, p_n) \equiv i_1^p p_0 i_2^p p_1 i_2^p p_2 \ldots i_2^p p_n$$

(where $i_1^p p_n$ is $i_1^p p_n$ or $i_2^p p_n$ according to whether $n$ is even or odd) is an equivalence.

**Proof.** That the wedge is connected follows by transitivity of identifications, if necessary passing through the identification $g : i_1 a_1 = i_2 a_2$ in the wedge.

We must prove that the wedge is a groupoid, i.e., that all identity types are sets, which we do by giving an explicit description of the universal set bundle.

We use the notation of Definition 4.16.1 freely, and for ease of notation, let $a_{2k+1} \equiv a_i$ and $i_{2k+1}^k \equiv i_i^k$ for $i = 1, 2, k : \mathbb{N}$. Define families of sets

$$C_i : A_i \rightarrow \text{Set}, \quad i = 1, 2$$

by

$$C_i(x) \equiv (a_i = A_i, x) \times \sum_{n : \mathbb{N}} \prod_{1 \leq k \leq n} \sum_{p_k : a_i = a_{i+k}} (p_k \neq \text{refl}_{a_{i+k}})$$

when $x : A_i$. Note that $p_k \neq \text{refl}_{a_{i+k}}$ is a proposition; we leave it out when naming elements. Hence, an element in $C_1(a)$ is a tuple $(p_0, n, p_1, \ldots, p_n)$
where \( p_0 : a_1 = A_1 \), \( p_1 : a_2 = A_2 \), \( p_2 : a_1 = A_1 \), and so on – alternating between symmetries of \( a_1 \) and \( a_2 \), and where \( p_0 \) is the only identity allowed to be \( \text{refl} \). Define \( C_{12} : C_1(a_1) \to C_2(a_2) \) by

\[
C_{12}(p_0, n, p_1, \ldots, p_n) = \begin{cases} 
(\text{refl}_{a_2}, 0) & \text{if } p_0 = \text{refl}_{a_1}, n = 0, \\
(p_1, n - 1, p_2, \ldots, p_n) & \text{if } p_0 = \text{refl}_{a_1}, n \neq 0, \\
(\text{refl}_{a_2}, n + 1, p_0, \ldots, p_n) & \text{if } p_0 \neq \text{refl}_{a_1}.
\end{cases}
\]

It is perhaps instructive to see a table of the values \( C_{12}(p_0, n, p_1, \ldots, p_n) \) for \( n < 3 \):

| \( p_0 = \text{refl}_{a_1} \) | \( (p_0, 0) \) | \( (p_0, 1, p_1) \) | \( (p_0, 2, p_1, p_2) \) |
| \( p_0 \neq \text{refl}_{a_1} \) | \( (\text{refl}_{a_2}, 0) \) | \( (p_1, 0) \) | \( (p_1, 1, p_2) \) |

Since \( C_{12} \) is an equivalence, the triple \( (C_1, C_2, C_{12}) \) defines a family

\[
C : A_1 \lor A_2 \to \text{Set}.
\]

In particular, \( C(a_{12}) \equiv C(a_1) \). For \( x : A_1 \) we let \( i_1^C : C_1(x) \to C(i_1(x)) \) be the induced equivalence, and likewise for \( i_2^C \). We will show that \( C \) is equivalent to \( P \equiv P_{a_{12}} \), where \( P(x) \equiv (a_{12} = x) \), and so that the identity types in the wedge are equal to the sets provided by \( C \).

One direction is by transport in \( C \); more precisely,

\[
a : \prod_{x : A_1 \lor A_2} (P(x) \to C(x))
\]

is given by transport with \( a(a_{12})(\text{refl}_{a_{12}}) \equiv (\text{refl}_{a_1}, 0) : C(a_{12}) \). The other way,

\[
\beta : \prod_{x : A_1 \lor A_2} (C(x) \to P(x))
\]

is given by composing identities, using the glue \( g \) to make their ends meet:

\[
\beta(i_1 a)(p_0, n, p_1, \ldots, p_n) \equiv i_1(p_0)i_2^C(p_1)i_3^C(p_2)\ldots i_{n+1}^C(p_n)
\]

(here the definition \( i_3^C \equiv i_1^C \equiv i_1 \) proves handy since we don’t need to distinguish the odd and even cases) and likewise

\[
\beta(i_2 a)(p_0, n, p_1, \ldots, p_n) \equiv i_2(p_0)g i_1^C(p_1)i_2^C(p_2)\ldots i_n^C(p_n)
\]

and compatibility with the glue \( C_{12} \) is clear since the composite \( \text{refl}_x p \) is equal to \( p \).

For notational convenience, we hide the \( x \) in \( a(x)(p) \) and \( \beta(x)(p) \) from now on.

That \( \beta a(p) = p \) follows by path induction: it is enough to prove it for \( x = a_{12} \) and \( p \equiv \text{refl}_{a_{12}} \):

\[
\beta a(\text{refl}_{a_{12}}) = \beta(\text{refl}_{a_1}, 0) = i_1^C \text{refl}_{a_1} = \text{refl}_{a_{12}}.
\]

That \( a \beta(p_0, n, p_1, \ldots, p_n) = (p_0, n, p_1, \ldots, p_n) \) follows by induction on \( n \) and \( p_0 \). For \( n = 0 \) it is enough to consider \( x = a_{12} \) and \( p_0 = \text{refl}_{a_1} \), and then \( a \beta(\text{refl}_{a_1}, 0) \equiv a(\text{refl}_{a_{12}}) \equiv (\text{refl}_{a_1}, 0) \). In general, (for \( n > 0 \))

\[
a \beta(p_0, n, p_1, \ldots, p_n) = \text{trp}_{i_1(p_0)i_2^C(p_1)i_3^C(p_2)\ldots i_{n+1}^C(p_n)}(\text{refl}_{a_1, 0})
\]

\[
= \text{trp}_{i_1(p_0)} \ldots \text{trp}_{i_{n+1}^C(p_n)}(\text{refl}_{a_1, 0}).
\]
The induction step is as follows: let \( 0 < k \leq n \), then
\[
\text{trp}_{p_{k-1}}^C i_{k-1}^C (p_k, n - k = 1, p_{k+1}, \ldots, p_n) \\
= \text{trp}_{p_{k-1}}^C i_k^C (\text{refl}_{n-k}, n - k, p_k, \ldots, p_n) \\
= i_k^C \text{trp}_{p_{k-1}}^C (\text{refl}_{n-k}, n - k, p_k, \ldots, p_n),
\]
\[
= (p_{k-1}, n - k, p_k, \ldots, p_n).
\]
\( \square \)

4.17 Heaps (†)

Recall that we in Remark 4.2.4 wondered about the status of general identity types \( a =_A a' \), for \( a \) and \( a' \) elements of a groupoid \( A \), as opposed to the more special loop types \( a =_A a \). Here we describe the resulting algebraic structure and how it relates to groups.

We proceed in a fashion entirely analogous to that of Section 4.2, but instead of looking a pointed types, we look at bipointed types.

**Definition 4.17.1.** The type of bipointed, connected groupoids is the type
\[
\mathcal{U}_n^1 := \sum_{A : \mathcal{U}^1} (A \times A).
\]

Recall that \( \mathcal{U}^1 \) is the type of connected groupoids \( A \), and that we also write \( A : \mathcal{U} \) for the underlying type. We write \( (A, a, a') : \mathcal{U}_n^1 \) to indicate the two endpoints.

Analogous to the loop type of a pointed type, we have a designated identity type of a bipointed type, where we use the two points as the endpoints of the identifications: We set \( I(A, a, a') \doteq (a =_A a') \).

**Definition 4.17.2.** The type of heaps\(^{44}\) is a wrapped copy (cf. Section 2.12.8) of the type of bipointed, connected groupoids \( \mathcal{U}_n^1 \),
\[
\text{Heap} \doteq \text{Copy}_I^1 (\mathcal{U}_n^1),
\]
with constructor \( I : \mathcal{U}_n^1 \to \text{Heap} \).

We call the destructor \( B : \text{Heap} \to \mathcal{U}_n^1 \), and call \( BH \) the classifying type of the heap \( H \equiv BH \), just as for groups, and we call the first point in \( BH \) is start shape of \( H \), and the second point the end shape of \( H \).

The identity type construction \( I : \mathcal{U}_n^1 \to \text{Set} \) induces a map \( I : \text{Heap} \to \text{Set} \), mapping \( I X \) to \( I X \). These are the underlying identifications of the heaps.

These is an obvious map (indeed a functor) from groups to heaps, given by doubling the point. That is, we keep the classifying type and use the designated shape as both start and end shape of the heap. In fact, this map lifts to the type of heaps with a chosen identification.

**Exercise 4.17.3.** Define natural equivalences \( \text{Heap} \cong \sum_G : \text{Group} BG \), and \( \text{Group} \cong \sum_H : \text{Heap} (UH) \).

Recalling the equivalence between \( BG \) and the type of \( G \)-torsors from Theorem 4.8.6, we can also say that a heap is the same as a group \( G \) together with a \( G \)-torsor.\(^{46}\) It also follows that the type of heaps is a (large) groupoid.

\(^{44}\)The concept of heap (in the abelian case) was first introduced by Prüfer\(^{45}\) under the German name Schen Gruppen”. In Anton Sushkevich’s book Теория Обобщенных Групп (Theory of Generalized Groups, 1937), the Russian term группа (heap) is used in contrast to группа (group). For this reason, a heap is sometimes known as a “groud” in English.

\(^{46}\)But be aware that are rare such descriptions, according to which end-point is the designated shape, and which is the “twisted” torsor.
In the other direction, there are two obvious maps (functors) from heaps to groups, taking either the start or the end shape to be the designated shape.

Here’s an a priori different map from heaps to groups: For a heap \( H \), consider all the symmetries of the underlying set of identifications \( U_H \) that arise as \( r \mapsto p q^{-1} r \) for \( p, q \in U_H \).

Note that \((p, q)\) and \((p', q')\) determine the same symmetry if and only if \( p q^{-1} = p' q'^{-1} \), and if and only if \( p'^{-1} p = q'^{-1} q \).

For the composition, we have \((p, q)(p', q') = (p q^{-1} p', q') = (p, q' p'^{-1} q)\).

**Exercise 4.17.4.** Complete the argument that this defines a map from heaps to groups. Can you identify the resulting group with the symmetry group of the start or end shape? How would you change the construction to get the other endpoint?

**Exercise 4.17.5.** Show that the symmetry groups of the two endpoints of a heap are merely isomorphic.

Define the notion of an abelian heap, and show that for abelian heaps, the symmetry groups of the endpoints are (purely) isomorphic.

Now we come to the question of describing the algebraic structure of a heap. Whereas for groups we can define the abstract structure in terms of the reflexivity path and the binary operation of path composition, for heaps, we can define the abstract structure in terms of a ternary operation, as envisioned by the following exercise.

**Exercise 4.17.6.** Fix a set \( S \). Show that the fiber \( U^{-1}(S) \equiv \sum_{H: \text{Heap}(S = UH)} \) is a set.

Now fix in addition a ternary operation \( t: S \times S \times S \to S \) on \( S \). Show that the fiber of the map \( \text{Heap} \to \sum_{S: \text{Set}(S \times S \times S \to S)} \), mapping \( H \) to \((UH, (p, q, r) \mapsto p q^{-1} r)\), at \((S, t)\) is a proposition, and describe this proposition in terms of equations.
5

Subgroups

5.1 Brief overview of the chapter

TBW (and stolen from the below)

5.2 Subgroups

In our discussion of the group $\mathbb{Z} \cong \text{Aut}_\mathbb{Z}(\bullet)$ of integers in Chapter 3 we discovered that some of the symmetries of $\bullet$ were picked out by the $n$-fold covering (for some particular natural number $n$). On the level of the set $\bullet \rightarrow \bullet$, the symmetries picked out are all the iterates (positive or negative or even zero-fold) of $\circ^n$. The important thing is that we can compose or invert any of the iterates of $\circ^n$ and get new symmetries of the same sort (because of distributivity $nm_1 + nm_2 = n(m_1 + m_2)$). So, while we do not get all symmetries of $\bullet$ (unless $n = 1$), we get what we’d like to call a subgroup of the group of integers.

The other extreme of the idea of a subgroup was exposed in Section 4.11.6 in the form of the slogan “any symmetry is a symmetry in Set”. By this we meant that, if $G \cong \text{Aut}_A(a)$ is a group, we produced a monomorphism $\rho_G : \text{Hom}(G, \text{Aut}_{\text{Set}}(\text{Set}))$, i.e., any symmetry of $a$ is uniquely given by a symmetry (“permutation”) of the set $\text{UG} \equiv (a \rightarrow a)$.

For yet another example, consider the cyclic group $C_6$ of order 6; perhaps visualized as the rotational symmetries of a regular hexagon, i.e., the rotations by $2\pi \cdot m/6$, where $m = 0, 1, 2, 3, 4, 5$. The symmetries of the regular triangle (rotations by $2\pi \cdot m/3$, where $m = 0, 1, 2$) can also be viewed as symmetries of the hexagon. Thus there is a subgroup of $C_6$ which, as a group, is isomorphic to $C_3$. There are other subgroups of $C_6$, and in this example they are accounted for simply by the various factorizations of the number 6.

For other groups the subgroups form more involved structures and reveal much about the nature of the object whose symmetries we study. There are several ways to pin down the subgroups and so capture this information. If $A$ is a groupoid, singling out a group of subsymmetries of $a : A$ should be a way of picking out just some of the symmetries of $a$ in $A$ in a way so that we can compose subsymmetries compatibly. To make a long story short; we want a group $H$ and a homomorphism $i : \text{Hom}(H, G)$ so that $U_i : UH \rightarrow UG$ is injective.$^1$ We have a name for such a setup: $i$ is a monomorphism as laid out in different interpretations in Lemma 4.11.3.

$^1$In classical set theory there is an important difference between saying that a function is the inclusion of a subset (which is what one classically wants) and saying that it is an injection. We’ll address this in a moment, so rest assured that all is well as you read on.
5.2.1 Subgroups as monomorphisms

The proposition isMono(i) is equivalent to saying that \( U_i : U_H \to U_G \) is an injection (all preimages of \( U_i \) are propositions), and also to saying that \( Bi : BH \to BG \) is a set bundle, which in turn is equivalent to the proposition isSet((B)i)(shC) since \( BG \) is connected.

**Definition 5.2.2.** If \( G \) is a group, the *type of monomorphisms into \( G \)* is

\[
\text{Mono}_G \equiv \sum_{H : \text{Group}} \sum_{i : \text{Hom}(H, G)} \text{isMono}(i)
\]

and the *type of epimorphisms from \( G \)* is

\[
\text{Epi}_G \equiv \sum_{H : \text{Group}} \sum_{f : \text{Hom}(G, G')} \text{isEpi}(f).
\]

A monomorphism \((H, i, !)\) is

1. **trivial** if \( H \) is the trivial group,
2. **proper** if \( i \) is not an isomorphism.

**Exercise 5.2.3.** (1) Show that \( i : \text{Hom}(H, G) \) is a monomorphism if and only if \( U_i \) is an injection of sets and that \( i \) is proper if and only \( U_i \) is not a bijection.

(2) Show that \( f : \text{Hom}(G, G') \) is a monomorphism if and only if \( \text{U}f \) is an surjection of sets.

(3) Consider a composite \( f = f_0f_2 \) of homomorphisms. Show that \( f_0 \) is an epimorphism if \( f \) is and \( f_2 \) is a monomorphism if \( f \) is.

**Example 5.2.4.** Consider the homomorphism \( i : \Sigma_2 \to \Sigma_3 \) of permutation groups corresponding to sending \( A : \Sigma_2 \equiv \text{FinSet}_2 \) to \( A + 1 : \Sigma_3 \).

**Example 5.2.5.** If \( G_1 \) and \( G_2 \) are groups, then the first projection from \( G_1 \times G_2 \) is an epimorphism and the first inclusion into \( G_1 \times G_2 \) is a monomorphism because their composite is the identity.

We will be interested in knowing when two monomorphisms into \( G \) are identical.

**Lemma 5.2.6.** Let \( G \) be a group and \((H, i_H, !), (H', i_{H'}, !) : \text{Mono}_G \) be two monomorphisms into \( G \). The identity type \((H, i_H, !) \sim (H', i_{H'}, !) \) is equivalent to

\[
\sum_{f : \text{Hom}(H, H')} \text{isEquiv}(Uf) \times (i_{H'} \sim i_H f)
\]

and is a proposition. In particular, the type \( \text{Mono}_G \) of monomorphisms into \( G \) is a set.

**Proof.** By Lemma 2.10.3 an identity between \((H, i_H, !)\) and \((H', i_{H'}, !)\) is uniquely given by an identity \( p : H' \to \text{Group}H \) such that \( i_{H'} \sim i_H p \) (a proposition since \( \text{Hom}(H', G) \) is a set). The description of the identity type follows since by univalence and Corollary 2.17.9(2), the identity type \( H \sim H' \) is equivalent to the set

\[
\sum_{f : \text{Hom}(H, H')} \text{isEquiv}(Uf).
\]

Now, \( i_{H'} \sim i_H f \) is equivalent to \( U_{i_{H'}} \sim U_{i_H} Uf \), and since \( U_{i_H} \) is an injection of sets there is at most one such function \( Uf \); translating back we see that there is at most one \( f \), making \( \sum_f \text{isEquiv}(Uf) \times (i_{H'} \sim i_H f) \) a proposition.

That \( i : \Sigma_2 \to \Sigma_3 \) is a monomorphism can visualized as follows: if \( \Sigma_3 \) represent all symmetries of an equilateral triangle in the plane (with vertices 1, 2, 3), then \( i \) is represented by the inclusion of the symmetries leaving 3 fixed; i.e., reflection through the line marked with dots in the picture.
5.2.7 Subgroups through G-sets

For many purposes it is useful to define “subgroups” slightly differently. A monomorphism into $G$ is given by a pointed connected groupoid $BH = (BH, pt_H)$, a function $F : BH \to BG$, whose fibers are sets (a set bundle) and an identification $p_F : shC \Rightarrow F(shH)$. There is really no need to specify that $BH$ is a groupoid: if $F : T \to BG$ is a set bundle, then $T$ is automatically a groupoid.

On the other hand, the type of set bundles over $BG$ is equivalent to the type of $G$-sets: if $X : BG \to Set$ is a $G$-set, then the set bundle is given by the first projection $X \to BG$ where $X := \sum_{y : BG} X(y)$ and the inverse is obtained by considering the fibers of a set bundle. Furthermore, we saw in Lemma 4.7.13 that $X$ being connected is equivalent to the condition isTrans($X$) of Definition 4.7.11 claiming that the $G$-set $X$ is transitive.

Hence, the type (set, really) $\text{Mono}_G$ of monomorphisms into $G$ is equivalent to the type of pointed connected set bundles over $BG$, which again is equivalent to the type $\text{Sub}_G$ of transitive $G$-sets $X : BG \to Set$ together with a point in $X(shC)$.

**Definition 5.2.8.** Let $G$ be a group then the set of subgroups of $G$ is

$$\text{Sub}_G := \sum_{X : BG \to Set} X(shC) \times \text{isTrans}(X).$$

The preferred equivalence with the set of monomorphisms into $G$ is given by the function $E : \text{Mono}_G \to \text{Sub}_G$. 

$$E : \text{Mono}_G \to \text{Sub}_G \quad (H, i, !) \mapsto E(H, i, !) \equiv ((Bi)^{-1}, (shH, p_i), !),$$

where the monomorphism $i : \text{Hom}(H, G)$ is – as always – given by the pointed map $(Bi, p_i) : (BH, shH) \to (BG, shC)$; and where the preimage $(Bi)^{-1} : BG \to Set$ is a $G$-set since $i$ is a monomorphism and finally $(shH, p_i) : (Bi)^{-1}(shC) \equiv \sum_{X : BG} X((shC) \Rightarrow Bi(x)).$

**Example 5.2.9.** The monomorphism of $\Sigma_2$ into $\Sigma_3$ of Example 5.2.4 can be displayed as a subgroup of $\Sigma_3$ through

$$X : \text{FinSet}_3 \to Set$$

given by $A \mapsto \sum_{B : \text{FinSet}_2} (A \Rightarrow B + 1)$ together with a proof that this is a set; in fact, the identity type $(B, p) \Rightarrow (B', p')$ is equivalent to $\sum_{q : B = B'} (q + 1)p \Rightarrow p'$ which is a proposition since $q$ is uniquely given by $q + 1 \Rightarrow p'p^{-1}$.

**Exercise 5.2.10.** Given a group $G$ we defined in Section 4.11.6 a monomorphism from $G$ to the permutation group $\text{Aut}(\text{Set})$. Write out the corresponding subgroup of $\text{Aut}(\text{Set})$.

**Example 5.2.11.** We saw in Example 5.2.5 that the first inclusion $i_1 : G \to G \times G'$ is a monomorphism. The corresponding $G \times G'$-set is the composite of the first projection $\text{proj}_1 : BG \times BG' \to BG$ followed by the principal $G$-torsor $\text{Pr}_G : BG \to Set$.

More generally, if $i : \text{Hom}(H, G)$ and $f : \text{Hom}(G, H)$, and $fi \Rightarrow id_H$, then $(H, i, !) : \text{Mono}_G$, corresponding to the subgroup with $G$-set given by the composite of $Bf$ with the principal $H$-torsor $\text{Pr}_H$.

Translating the concepts in Definition 5.2.2 through the equivalence $E$ we say that a subgroup $(X, pt, !) : \text{Sub}_G$ is
(1) **trivial** if \( X \) is identical to the principal \( G \)-torsor.

(2) **proper** if \( X(\text{sh}_C) \) is not contractible.

**Remark 5.2.12.** A note on classical notation is in order. If \((X, \text{pt}, !)\) is a subgroup corresponding to a monomorphism \((H, i, !)\) into a group \( G \), tradition would permit us to relax the burden of notation and we could write "a subgroup \( i : H \subseteq G \)" or, if we didn’t need the name of \( i : \text{Hom}(H, G) \), simply "a subgroup \( H \subseteq G \)" or "a subgroup \( H \) of \( G \)."

### 5.3 Images, kernels and cokernels

The set of subgroups of a group \( G \) encodes much information about \( G \), partially because homomorphisms between \( G \) and other groups give rise to subgroups.

In Example 4.2.22 we studied a homomorphism from \( Z \) to \( \Sigma_m \) defined via the pointed map \( R_m : S^1 \to \mathcal{B} \Sigma_m \) given by sending \( \cdot \) to \( m \) and \( \cup \) to the cyclic permutation \( s_m : \Sigma_m \equiv (m \sim m) \), singling out the iterates of \( s_m \) among all permutations. From this we defined the group \( C_m \) through a quite general process which we define in this section, namely by taking the **image** of \( R_m \).

We also noted that the resulting pointed map from \( S^1 \) to \( BC_m \) was intimately tied up with the \( m \)-fold set bundle \(-m : S^1 \to S^1 \) - picking out exactly the iterates of \( \cup^m \) - which in our current language corresponds to a monomorphism \( i_m : \text{Hom}(Z, Z) \). This process is also a special case of something, namely the **kernel**.

The relations between the cyclic groups in the forms \( Z/m, C_m \) and \( C_m' \) as in Example 4.2.21 are also special cases of what we do in this section.

In our setup with a group homomorphism \( f : \text{Hom}(G, G') \) being given by a pointed function \( Bf : BG \to BG' \), the above mentioned kernel, cokernel and image are just different aspects of the preimages

\[
(Bf)^{-1}(z) \equiv \sum_{x : BG} (z \sim Bf(x))
\]

for \( z : BG' \). Note that all these preimages are groupoids.

The kernel will correspond to a preferred component of the preimage of \( \text{sh}_C \), the cokernel will be the \((G')\)-set of components and for the image we will choose the monomorphism into \( G' \) corresponding to the cokernel. This point of view makes it clear that the image will be a subgroup of \( G' \), the kernel will be a subgroup of \( G \), whereas there is no particular reason for the cokernel to be more than a \((G')\)-set.

### 5.3.1 Kernels and cokernels

The kernel of \( f : \text{Hom}(G, G') \) is an abstract subgroup \( \ker f \), whereas the cokernel is the set of components of the fiber. We spell out the details.

**Definition 5.3.2.** We define a function

\[
\ker : \text{Hom}(G, G') \to \text{Mono}_C
\]

which we call the **kernel**. If \( f : \text{Hom}(G, G') \) is a homomorphism we must specify the ingredients in \( \ker f \equiv (\text{Ker} f, \text{in}_{\ker f}, !) : \text{Mono}_C \). The
classifying $B\ker f$ space of the kernel group (or most often just the “kernel”) is the component of the fiber of $Bf$ pointed by
\[ \text{sh}_{\ker f} : (\text{sh}_G, p_f) \mapsto (Bf)^{-1}(\text{sh}_G) \]
(where $p_f : \text{sh}_G \to Bf(\text{sh}_G)$ is the part of $Bf$ claiming it is a pointed map).

The first projection $B \ker f \to BG$ is a set bundle (by Corollary 2.9.11 the preimages are equivalent to the sets $\sum_{p : \text{sh}_G} Bf(z, p)$) giving a monomorphism $\text{in}_{\ker f}$ of $\ker f$ into $G$; together defining $\ker f : \equiv (\ker f, \text{in}_{\ker f}, 1) : \text{Mono}_G$.

Written out, the classifying type of the kernel, $B\ker f$, is
\[ \sum_{z : BG} \sum_{p : \text{sh}_G} ||(\text{sh}_G, p_f) \mapsto (z, p)|| \]
and $\text{in}_{\ker f} : \text{Hom}(\ker f, G)$ is given by the first projection.

**Definition 5.3.3.** Let $f : \text{Hom}(G, G')$ be a homomorphism. The *cokernel* of $f$ is the $G'$-set
\[ \text{coker } f : BG' \to \text{Set}, \quad \text{coker } f(z) : ||(Bf)^{-1}(z)||_0; \]
defining a function of sets
\[ \text{coker} : \text{Hom}(G, G') \to G'$-Set. \hfill \qed \]

If a monomorphism $i$ from $G$ to $G'$ is clear from the context (“$G \subseteq G'$”), we may write $G'/G$ for the cokernel of $i$.

**Lemma 5.3.4.** The cokernel $\text{coker } f$ is a transitive $G'$-set.

**Proof.** It is enough to show that for all $x, p \in \text{coker}(\text{sh}_{G'}$) there is a $g : U \ni (\text{sh}_G, p_f) \mapsto (x, p)$. It suffices to do this for $x$ being $\text{sh}_G$, and then $g \equiv p_f^{-1}p$ will do. \hfill \qed

**Remark 5.3.5.** Since the cokernel is a transitive $G'$-set, we need just to provide $\text{coker } f(\text{sh}_{G'}) : \equiv ||(Bf)^{-1}(\text{sh}_{G'})||_0$ with a point to say that the cokernel defines a subgroup of $G'$. The obvious point to choose is $||\text{sh}_G, p_f||$. In the next section we will consider this subgroup in more detail and call it the image of $f$.

Another proof of cokernel $f$ being a transitive $G'$-set would be to say that since $BG$ is connected and equivalent to $\sum_{z : BG} Bf^{-1}(z)$ which maps surjectively onto $\sum_{z : BG} ||Bf^{-1}(z)||_0$ the latter is connected – and, when pointed at $(\text{sh}_{G'}, [\text{sh}_G, p_f])$, just another name for $E(\text{coker } f) : \text{Mono}_{G'}$. \hfill \qed

**Exercise 5.3.6.** Given a homomorphism $f : \text{Hom}(G, G')$, prove that

1. $f$ is a monomorphism if and only if the kernel is trivial
2. $f$ is an epimorphism if and only if the cokernel is contractible.
3. if $h : \text{Hom}(L, G)$ is a homomorphism such that $fh : \text{Hom}(L, G')$ is the trivial homomorphism (equivalently, $fh$ factors through the trivial group 1), then there is a unique $k : \text{Hom}(L, \ker f)$ such that $h \mapsto \text{in}_{\ker f} k$. \hfill \qed

The kernel, cokernel and image constructions satisfy a lot of important relations which we will review in a moment, but in our setup many of them are just complicated ways of interpreting the following fact about preimages (see the illustration² in the margin for an overview)

```
\[
\text{sh}_{\ker f} = \text{Aut}(\text{sh}_{G'})\text{sh}_{G}
\]
```

that is
\[ \ker f : \equiv \text{Aut}(\text{sh}_{G'}) \text{sh}_{G} \]

The associated $\text{abs}(G')$-set cokernel $f(\text{sh}_{G'})$ is (also) referred to as the (abstract) cokernel of $f$.

The subgroup of $G'$ associated with the cokernel is the “image” of the next section.

Hint: consider the corresponding property of the preimage of $Bf$.
Lemma 5.3.7. Consider pointed functions $(f_1, p_1): (X_0, x_0) \to (X_1, x_1)$ and $(f_2, p_2): (X_1, x_1) \to (X_2, x_2)$ and the resulting functions

\[ F_1: f_1^{-1}(x_1) \to (f_2 f_1)^{-1}(x_2), \quad F_1(x, p) \equiv (x, p_2 f_2 p), \]
\[ F_2: (f_2 f_1)^{-1}(x_2) \to f_2^{-1}(x_2), \quad F_2(x, q) \equiv (f_1 x, q) \]
\[ H: F_2^{-1}(x_1, p_2) \to f_1^{-1}(x_1), \quad H(x, q, (p, r)) \equiv (x, p) \]

Then

1. $H$ is an equivalence with inverse

\[ H^{-1}(x, q) \equiv ((x, p_2 f_2(q)), (q, \text{refl}_{p_2 f_2(q)})) \]

2. The composite $F_1 H$ is identical to the first projection

\[ \text{fst}: F_2^{-1}(x_1, p_2) \to (f_2 f_1)^{-1}(x_2), \]

more precisely, if $(x, q, (p, r)) \in F_2^{-1}(x_1, p_2)$, then $\text{fst}(x, q, (p, r)) = (x, q)$, whereas $F_1 H(x, q, (p, r)) = (x, p_2 f_2 p)$ and $r : p_2 f_2 p \to q$ provides the desired element in $F_1 H \cong \text{fst}$.

Proof. That $H$ is an equivalence is seen by noting that $F_2^{-1}(x_1, p_2)$ is equivalent to $\{ x : x_0 \xrightarrow{f_1} f_1^{-1}(x_1) \}$ of function with codomain $(f_2 f_1)^{-1}(x_2)$.

From the universal property of the preimage it furthermore follows that $F$ is the unique map such that $\text{fst} F \cong f_1^{-1}(x_1) \to X_0 \xrightarrow{f_1} X_1$ and $H^{-1}$ is similarly unique with respect to $\text{fst} H^{-1} \cong F$.

Corollary 5.3.8. Consider two composable homomorphisms $f_1 : \text{Hom}(G_0, G_1)$ and $f_2 : \text{Hom}(G_1, G_2)$. There is a unique monomorphisms $F_1$ from $\text{Ker } f_1$ to $\text{Ker } (f_2 f_1)$ and a unique homomorphism $F_2$ from $\text{Ker } (f_2 f_1)$ to $\text{Ker } f_2$ such that $\text{in}_{\text{Ker } f_1} \cong \text{in}_{\text{Ker } f_2 f_1} F_1$ and $\text{id}_{\text{in}_{\text{Ker } f_2 f_1}} \cong \text{in}_{\text{Ker } f_2} F_2$. Furthermore,

\[ F_1 \cong \text{Monog}_{G_1} \text{in}_{\text{Ker } F_1} \]

and

\[ (\text{coker } f_1) \text{Bker } f_1 \cong \text{Bker } f_2 \xrightarrow{\text{Set} coker(F_2)} \text{coker } F_2. \]

Consequently,

1. If $f_2$ is a monomorphism then $F_1 : \text{Ker } f_1 \to \text{Ker } f_2 f_1$ is an isomorphism and

2. If $f_1$ is a monomorphism then $F_2 : \text{Ker } f_2 f_1 \to \text{Ker } f_2$ is an isomorphism.

Likewise, the set truncation of the maps $F_1$ and $F_2$ constructed in Lemma 5.3.7 give maps of families

\[ F_1 : \text{coker } f_1 \to \text{Set } \text{coker}(f_2 f_1) \text{ Bf}_2, \quad F_2 : \text{coker}(f_2 f_1) \to \text{Set } \text{coker } f_2 \]

such that

(here the function $(x_1, p_2) \xrightarrow{(f_2(x, q))} (x_1) \xrightarrow{f_1(x)} (x_1)$ is the “first projection” explained in the discussion of the interpretation of pairs following Definition 2.10.1)
(1) If $f_2$ is an epimorphism then $F_1: \text{coker } f_1 \to \text{Set} \text{ coker}(f_2 f_1) B f_2$ is an equivalence and

(2) If $f_1$ is an epimorphism then $F'_1: \text{coker}(f_2 f_1) \to \text{Set} \text{ coker } f_2$ is an equivalence.

**Exercise 5.3.9.** Let $f: \text{Hom}(G, G')$. Then the subgroup $E(\ker f): \text{Sub}_{G'}$ associated with the kernel is given by a $G$-set equivalent to the one sending $x: BG$ to

$$\sum_{p: sh_{G'} \overset{\sim}{\to} B f(x)} \parallel \sum_{p: sh_{G'} \overset{\sim}{\to} x} p \Rightarrow U f(\beta)p/||.$$

If $f$ is an epimorphism this is furthermore equivalent to

$$x \mapsto (sh_{G'} \overset{\sim}{\to} B f(x)).$$

### 5.3.10 The image

For a function $f: A \to B$ of sets (or, more generally, of types) the notion of the “image” gives us a factorization through a surjection followed by an injection: noting that $a \mapsto (f(a), !)$ is a surjection from $A$ to the “image” $\sum_{b: B} ||f^{-1}(b)||$, from which we have an injection (first projection) to $B$. This factorization

$$A \to \sum_{b: B} ||f^{-1}(b)|| \to B$$

is unique (Exercise 2.17.12).

For a homomorphism $f: \text{Hom}(G, G')$ of groups we similarly have a unique factorization

$$G \to \text{Im } f \to G'$$

through an epimorphism followed by a monomorphism which, on the level of connected groupoids, is given by

$$BG \xrightarrow{x \mapsto (B f(x), [(x, \text{refl}_{B f(x)})]_0)} \sum_{z: BG'} ||(B f^{-1}(z)||_0 \xrightarrow{\text{fst}} BG'.$$

Together with base point information. In particular, we choose the base point $(sh_{G'}, [(sh_{G'}, p f)]_0)$, so that the image group is

$$\text{Im } f \seteq \text{Aut}_{\sum_{z: BG'} ||(B f^{-1}(z)||_0} ((sh_{G'}, [(sh_{G'}, p f)]_0)).$$

In other words, the image is nothing but the subgroup of $G'$ associated with the cokernel as discussed in Remark 5.3.5.

**Exercise 5.3.11.** With the choice of point of $\text{Im } f$ above, give paths for $x \mapsto (B f(x), [(x, \text{refl}_{B f(x)})]_0)$ and $\text{fst}$ so that these maps become pointed maps whose composition is indeed equal to the pointed map $B f$. Show that these pointed maps indeed give an epimorphism and a monomorphism, respectively. Hint: for the epimorphism, use Lemma 3.9.6.

That the image gives a unique factorization is elegantly expressed by saying that it is the unique inverse of composition. We use the pullback construction from Definition 4.15.1 to express the type of epi/mono factorizations of homomorphisms from $G$ to $G'$ as $\text{Epi}_{G \times \text{Group}} \text{ Mono}_{G'}$ where the maps to Group are understood to be the first projections (so that the epimorphisms and monomorphisms in question can, indeed, be composed).
CONSTRUCTION 5.3.12. For all groups \( G \), and \( G' \) the map

\[
\circ : \text{Epi}_G \times \text{Group Mono}_{G'} \rightarrow \text{Hom}(G, G')
\]

given by composition,

\[
\circ((Z, p, l), (Z', j, l), \alpha) \equiv j \tilde{\alpha} p
\]
is an equivalence with inverse given by the image factorization.

Implementation of Construction 5.3.12. For any integer \( n \geq -1 \) and in our case for \( n = 0 \) – on the level of types the factorization of a function \( f : X \rightarrow Z \) as

\[
X \xrightarrow{x \mapsto (f(x), (x, \text{refl}(x))_n)} \sum_{z : Z} \|f^{-1}(z)\|_n \xrightarrow{\text{fst}} Z
\]
is unique in the sense that

if \( p : f \Rightarrow jq \) where \( q : X \rightarrow Y \) is so that for all \( y : Y \) the \( n \)-truncation of \( q^{-1}(y) \) is contractible and \( j : Y \rightarrow Z \) is so that for all \( z : Z \) the fiber \( j^{-1}(z) \) is \( n \)-truncated, then for each \( z : Z \) the function \( f^{-1}(z) \rightarrow j^{-1}(z) \) induced by \( (p \text{ and } q) \) gives an equivalence

\[
(j, q) : \|f^{-1}(z)\|_n \simeq j^{-1}(z)
\]
identifying (under univalence) the two factorizations of \( f \).

If \( X \) and \( Z \) are connected groupoids, then so is \( \sum_{z : Z} \|f^{-1}(z)\|_n \), and so when applying the factorization to groups (when \( n = 0 \)), the only thing we need to worry about is the base point. If if the point-data is given by \( x_0 : X \), \( y_0 : Y \), \( z_0 : Z \), \( p_q : y_0 \Rightarrow q(x_0) \), \( p_j : z_0 \Rightarrow j(y_0) \) and \( p_f : z_0 \Rightarrow f(x_0) \) with \( b : p_f \Rightarrow a_0^{-1}(p_q)p_j \), where \( a : \prod_{x : X} f(x) \Rightarrow j(q(x)) \) witnesses that we have a factorization, then we point \( \sum_{z : Z} \|f^{-1}(z)\|_n \) in \( (z_0, (x_0, p_f)_n) \) and note that the equivalence \( \sum_{z : Z} \|f^{-1}(z)\|_n \Rightarrow Y \) is pointed via \( p_q : y_0 \Rightarrow q(x_0) \) and

\[
b : z_0 \xrightarrow{p_f} f(x_0) \xrightarrow{a_0} j(q(x_0)).
\]

\[\square\]

DEFINITION 5.3.13. Explicitly, the image factorization for groups is the function

\[
\circ^{-1} : \text{Hom}(G, G') \rightarrow \text{Epi}_G \times \text{Group Mono}_{G'}
\]

\[
\circ^{-1}(f) \equiv ((\text{Im } f, \text{pr}_{\text{Im } f}, !), (\text{Im } f, \text{in}_{\text{Im } f}, !), \text{refl}_{\text{Im } f}),
\]

where as before the image group is the group

\[
\text{Im } f \equiv \text{Aut}_{\sum_{z : G} \text{coker } f(z)}(\text{sh}_{G'}, [(\text{sh}_G, p_f)]_0),
\]

the monomorphism \( \text{in}_{\text{Im } f} \) is obtained from the wrapping of the first projection

\[
\text{Bin}_{\text{Im } f} \equiv \text{fst} : B \text{ Im } f \rightarrow BG'
\]

\[\text{here } p \text{ is an epimorphism from } G \text{ to the group } Z, j \text{ a monomorphisms from the group } Z' \text{ to } G', a : Z \Rightarrow Z \text{ and } \tilde{a} \text{ is the isomorphism corresponding to the identification } a : Z \Rightarrow Z', \text{ as in Definition 2.13.1, so that the composite looks like}
\]

\[
G \xrightarrow{p} Z \xrightarrow{\tilde{a}} Z' \xrightarrow{j} G'
\]

\[\text{To see that the function is an equivalence notice that it can be obtained as follows: rewrite } f^{-1}(z) \text{ first as}
\]

\[
\sum_{x : X} \sum_{y : Y} (z \Rightarrow f(x)) \times (y \Rightarrow q(x)),
\]

then as

\[
\sum_{y : Y} \sum_{x : X} (z \Rightarrow j(y)) \times (y \Rightarrow q(x))
\]

and finally use that the \( n \)-truncation of \( \sum_{x : Y} z \Rightarrow q(x) \) is contractible

\[
\begin{array}{c}
X \\
\xrightarrow{f} \\
\xrightarrow{\text{fst}} Y \\
\xrightarrow{\text{in}_{\text{Im } f}} Z
\end{array}
\]
and the epimorphism \( pr_{\text{im}f} \) is given on the level of classifying types by sending \( x : BG \) to

\[
B pr_{\text{im}f}(x) := (B f(x), \langle x, \text{refl}_{B f(x)} \rangle_0) : B \text{im} f.
\]

Occasionally we may refer to the two projections of the image factorization

\[
im : \text{Hom}(G, G') \to \text{Mono}_{G'}, \quad \text{im}(f) \equiv (\text{im} f, \text{in}_{\text{im} f}, !)
\]

\[
pr^{\text{im}} : \text{Hom}(G, G') \to \text{Epi}_{G'}, \quad pr^{\text{im}} f \equiv (\text{im} f, pr_{\text{im} f}, !)
\]

as the image and the projection to the image.

In view of Exercise 5.3.14 below, the families

\[
\text{isepi}, \text{ismono} : \text{Hom}(G, G') \to \text{Prop}
\]

of propositions that a given homomorphism is an epimorphism or monomorphism have several useful interpretations (parts of the exercise have already been done).

**Exercise 5.3.14.** Let \( f : \text{Hom}(G, G') \) Prove that

1. the following are equivalent
   a) \( f \) is an epimorphism,
   b) \( Uf \) is a surjection
   c) the cokernel of \( f \) is contractible,
   d) the inclusion of the image \( \text{in}_{\text{im} f} : \text{Hom}(\text{im} f, G') \) is an isomorphism,

2. the following are equivalent
   a) \( f \) is a monomorphism,
   b) \( Uf \) is an injection
   c) the kernel of \( f \) is trivial
   d) \( B f : BG \to BG' \) is trivial
   e) the projection onto the image \( pr_{\text{im} f} : \text{Hom}(G, \text{im} f) \) is an isomorphism.

We need to understand how the image factorization handles composition of homomorphisms. This is forced by the uniqueness as follows.

**Lemma 5.3.15.** Given composable homomorphisms \( f_1 : \text{Hom}(G_0, G_1) \) and \( f_2 : \text{Hom}(G_1, G_2) \), unique factorization induces identifications

\[
im(\text{im}(f_2 f_1)) \equiv_{\text{Mono}_{G_2}} \langle \text{in}_{\text{im}(f_2 f_1)} \rangle \equiv_{\text{Mono}_{G_1}} \langle \text{in}_{\text{im}(f_2 f_1)} \rangle \equiv_{\text{Mono}_{G_0}} \langle \text{in}_{\text{im}(f_2 f_1)} \rangle
\]

\[
pr^{\text{im}}(\text{im}(f_2 f_1)) \equiv_{\text{Epi}_{G_2}} \langle \text{in}_{\text{im}(f_2 f_1)} \rangle \equiv_{\text{Epi}_{G_1}} \langle \text{in}_{\text{im}(f_2 f_1)} \rangle \equiv_{\text{Epi}_{G_0}} \langle \text{in}_{\text{im}(f_2 f_1)} \rangle
\]

**Proof.** Since composition preserves monomorphisms and epimorphisms – in particular \( \text{in}_{\text{im}(f_2 f_1)} : \text{Hom}(\text{im}(f_2 f_1), G_2) \) is a monomorphism and \( pr^{\text{im}}(\text{im}(f_2 f_1)) : \text{Hom}(\text{im}(f_2 f_1), G_2) \) is an epimorphism – this is just uniqueness of the image factorization of the composite \( f_2 f_1 \). \( \square \)
Lemma 5.3.16. Let \( f : \text{Hom}(G, G') \) be a group homomorphism. The induced map \((\text{pr}_{\text{im}} f)^{-1}(\text{sh}_{\text{im}} f) \to (Bf)^{-1}(\text{sh}_{G'})\) gives an identification

\[
\ker \text{pr}_{\text{im}} f \cong_{\text{Mono}} \ker f.
\]

Proof. Using univalence, this is a special case of Corollary 5.3.8 with \( f_2 \equiv \text{in}_{\text{im}} f \) and \( f_1 \equiv \text{pr}_{\text{im}} f \). \( \square \)

Exercise 5.3.17. (1) If \( f : \text{Mono}_{G} \), then \( u(a(\text{pr}_{\text{im}} f)) : f \cong_{\text{Mono}_{G}} \text{in}_{\text{im}} f \).

(2) If \( f : \text{Epi}_{G} \), then \( u(a(\text{in}_{\text{im}} f)) : f \cong_{\text{Epi}_{G}} \text{pr}_{\text{im}} f \).

(True propositions suppressed).

Example 5.3.18. An example from linear algebra: let \( A \) be any \( n \times n \)-matrix with nonzero determinant and with integer entries, considered as a homomorphism \( A : \text{Hom}(\mathbb{Z}^n, \mathbb{Z}^n) \). “Nonzero determinant” corresponds to “monomorphism”. Then the cokernel of \( A \) is a finite set with cardinality the absolute value of the determinant of \( A \). You should picture \( A \) as a \( |\det(A)| \)-fold set bundle of the \( n \)-fold torus \((S^1)^n\) by itself.

In general, for an \( n \times n \)-matrix \( A \), then the “nullspace” is given by the kernel and the “rowspace” is given by the image.

5.4 The action on the set of subgroups

Not only is the type of subgroups of \( G \) a set, it is in a natural way (equivalent to the value at \( \text{sh}_{G} \) of) a \( G \)-set which we denote by the same name. We first do the monomorphism interpretation

Definition 5.4.1. If \( G \) is the group, the \( G \)-set of monomorphisms into \( G \)

\[
\text{Mono}_{G} : BG \to \text{Set}
\]

is given by

\[
\text{Mono}_{G}(y) \equiv \sum_{H : \text{Group}} \sum_{f : \text{Hom}(H, G)(y)} \text{isSet}(Bf^{-1}(\text{sh}_{G}))
\]

for \( y : BG \), where – as in Example 4.7.5 –

\[
\text{Hom}(H, G)(y) \equiv \sum_{F : BH \to BG} (y \cong F(\text{sh}_{H}))
\]

is the \( G \)-set of homomorphisms from \( H \) to \( G \).

Definition 5.4.2. If \( G \) is a group, then the action of \( G \) on the set of monomorphisms into \( G \) is called conjugation.

If \((H, F, p, !) : \text{Mono}_{G}(\text{sh}_{G})\) is a monomorphism into \( G \) and \( g : UG \), then the monomorphisms \((H, F, p, !), (H, F, pg^{-1}, !) : \text{Mono}_{G}(\text{sh}_{G})\) are said to be conjugate.

Remark 5.4.3. The term “conjugation” may seem confusing as the action of \( G \) on a monomorphism \((H, F, p, !) : \text{Mono}_{G}(\text{sh}_{G})\) (where \( p : x \cong F(\text{sh}_{H}) \)) is simply \((H, F, pg^{-1}, !) \), which does not seem much like conjugation. However, as we saw in Example 4.13.2, under the equivalence \( \text{abs} : \text{Hom}(H, G) \cong \text{Hom}^{\text{abs}}(\text{abs}(H), \text{abs}(G)) \), the corresponding action on \( \text{Hom}^{\text{abs}}(\text{abs}(H), \text{abs}(G)) \) is exactly (postcomposition with) conjugation \( c^g : \text{abs}(G) \cong \text{abs}(G) \).

Summing up the remark:

6The same phenomenon appeared in Exercise 4.7.6 where we gave an equivalence between the \( G \)-sets \( \text{Hom}(\mathbb{Z}, G) \) and \( \text{Ad}_{G} \) (where the action is very visibly by conjugation).
Lemma 5.4.4. Under the equivalence of Lemma 4.13.1 between $G$-sets and $\text{abs}(G)$-sets, the $G$-set $\text{Mono}_G$ corresponds to the $\text{abs}(G)$-set

$$\sum_{H : \text{Group}} \sum_{\phi : \text{Hom}^{\text{abs}}(H, \text{abs}(G))} \text{isProp}(\phi^{-1}(e_G))$$

of abstract monomorphisms of $\text{abs}(G)$, with action $g \cdot (H, \phi, !) \equiv (H, c^g \phi, !)$ for $g : \text{abs}(G)$, where $c^g : \text{abs}(G) \xrightarrow{\sim} \text{abs}(G)$ is conjugation as defined in Example 4.4.25.

Remark 5.4.5. We know that a group $G$ is abelian if and only if conjugation is trivial: for all $g : U_G$ we have $c^g \xrightarrow{\sim} \text{id}$, and so we get that $\text{Mono}_G$ is a trivial $G$-set if and only if $G$ is abelian.

The subgroup analog of $y \mapsto \text{Mono}_G(y)$ is

Definition 5.4.6. Let $G$ be a group and $y : BG$, then the $G$-set of subgroups of $G$ is

$$\text{Sub}_G : BG \to \text{Set}, \quad \text{Sub}_G(y) \equiv \sum_{X : BG \to \text{Set}} X(y) \times \text{isTrans}(X).$$

The only thing depending on $y$ in $\text{Sub}_G(y)$ is where the “base” point is residing (in $X(y)$ rather than in $X(\text{sh}_G)$).

Definition 5.4.7. Extending the equivalence of sets we get an equivalence of $G$-sets $E : \text{Mono}_G \to \text{Sub}_G$ via

$$E(y) : \text{Mono}_G(y) \to \text{Sub}_G(y), \quad E(H, F, p_F, !) \equiv (F^{-1}, (\text{sh}_H, p_F), !)$$

for $y : BG$ (where $H$ is a group, $F : BH \to BG$ is a map and $p_F : y \xrightarrow{\sim} F(\text{sh}_H)$ an identity in $BG$; and $F^{-1} : BG \to \text{Set}$ is $G$-set given by the preimages of $F$ and $(\text{sh}_H, p_F) : F^{-1}(y) \equiv \sum_{x : BH} x \xrightarrow{\sim} F(x)$ is the base point). If $y$ is $\text{sh}_G$ we follow our earlier convention of dropping it from the notation.

Since the families are equivalent (via $E$) we use $\text{Mono}_G$ or $\text{Sub}_G$ interchangeably.

5.5 Normal subgroups

In the study of groups, the notion of a “normal subgroup” is of vital importance and, as for any important concept, it comes in many guises revealing different aspects. For now we just state the definition in the form that it is a subgroup “fixed under the action of $G$” on the $G$-set of subgroups.

Definition 5.5.1. The set of normal subgroups is

$$\text{Nor}_G \equiv \prod_{y : BG} \text{Sub}_G(y)$$

considered as a subset of $\text{Sub}_G$ via the injection

$$i : \text{Nor}_G \to \text{Sub}_G, \quad i(N) \equiv N(\text{sh}_G).$$

Remark 5.5.2. The function $i$ taking a fixed point of the action $\text{Sub}_G$ to its actual subgroups is indeed an injection. Given two normal subgroups
Restricting the equivalence $E : \text{Mono}_G \rightarrow \text{Sub}_G$ to the fixed sets, we get an equivalence from $\prod_{y : BG} \text{Mono}_G(y)$ to $\text{Nor}_G$.

We will achieve these goals by defining a function $\text{nor} : \text{Epi}_G \rightarrow \text{Nor}_G$ which we show is an equivalence and, furthermore, that the two functions $i_{\text{nor}}, Ei_{\ker} : \text{Epi}_G \rightarrow \text{Sub}_G$ are identical. Since $i_{\text{nor}}$ is an injection, this forces the surjection $\ker$ to be injective too and we are done.

**Definition 5.5.3.** If $G$ is a group, let

$$\begin{array}{ccc}
\text{Epi}_G & \xrightarrow{i_{\ker}} & \text{Ker}_G \supseteq \text{Mono}_G \\
\downarrow \text{ker} & & \downarrow \text{Mono}_G \\
\text{Nor}_G & \xrightarrow{i} & \text{Sub}_G
\end{array}$$

be the surjection/injection factorization of the kernel function restricted to the epimorphisms from $G$. We call the subset $\text{Ker}_G$ the set of kernels.

Our aim is twofold:

1. we want to show that $\ker : \text{Epi}_G \rightarrow \text{Ker}_G$ is an equivalence, so that knowing that a monomorphism is a kernel is equivalent to knowing an epimorphism it is the kernel of.

2. we want to show that the kernels correspond via the equivalence $E$ to the fixed points under the $G$ action on the $G$-set of subgroups.

For $x', y' : BG'$, recall the notation $P_{y'}(x') \equiv (y' \rightarrow x')$.

**Definition 5.5.4.** Define $\text{nor} : \text{Epi}_G \rightarrow \text{Nor}_G$

by $\text{nor}(G', f, !)(y) \equiv (P_{f(y)} f, \text{refl}_{f(y)}, !)$ for $y : BG$.

**Remark 5.5.5.** The $G$-set $P_{f(y)} f$ is not a $G$-torsor (except if $f$ is an isomorphism).

**Lemma 5.5.6.** The diagram

$$\begin{array}{ccc}
\text{Ker}_G & \xrightarrow{i_{\ker}} & \text{Mono}_G \\
\downarrow \text{ker} & & \downarrow \text{E} \\
\text{Epi}_G & \xrightarrow{i_{\text{nor}}} & \text{Nor}_G \\
\downarrow \text{nor} & & \downarrow \text{Sub}_G
\end{array}$$

commutes, where the top composite is the image factorization of the kernel and the bottom inclusion is the inclusion of fixed points.

**Proof.** Following $(G', f, !) : \text{Epi}_G$, around the top to $\text{Sub}_G$ yields the transitive $G$-set sending $y : BG$ to the set $\text{sh}_{G'} \rightarrow f(y)$ together with the point $p_f : \text{sh}_{G'} \rightarrow f(\text{sh}_{G'})$ while around the bottom we get the transitive
$G$-set sending $y : BG$ to the set $f(sh_G) \xrightarrow{\sim} f(y)$ together with the point \(refl_{f(sh_G)} : f(sh_G) \xrightarrow{\sim} f(sh_G)\). Hence, precomposition by $p_f$ gives the identity proving that the diagram commutes.

We will prove that both $\ker$ and $\nor$ in the diagram of Lemma 5.5.6 are equivalences, leading to the desired conclusion that the equivalence $E : \text{Mono}_G \xrightarrow{\sim} \text{Sub}_G$ takes the subset $\ker_G$ identically to $\nor_G$. Actually, since $\ker : \text{Epi}_G \rightarrow \ker_G$ is a surjection, we only need to know it is an injection, and for this it is enough to show that $\nor$ is an equivalence; we’ll spell out the details.

Since it has independent interest, we take a detour via a quotient group construction of Definition 5.5.8 which gives us the desired inverse of $\nor$. We start with a small, but crucial observation.

**Lemma 5.5.7.** Let $N : \nor_G$ be a normal subgroup with $N(y) \equiv (X_y, pt_y, !)$ for $y : BG$. Then for any $y, z : BG$

1. the evaluation map

$$\ev_{yz} : (X_y \xrightarrow{\sim} X_z) \rightarrow X_z(y), \quad \ev_{yz}(f) \xrightarrow{\sim} f_y(pt_y)$$

is an equivalence and

2. the map $X : (y \xrightarrow{\sim} z) \rightarrow (X_y \xrightarrow{\sim} X_z)$ (given by induction via $X_{\text{refl}_y} \equiv \text{refl}_{X_y}$) is surjective.

**Proof.** To establish the first fact we need to do induction independently on $y : BG$ and $z : BG$ in $X_y(z)$ at the same time as we observe that it suffices (since $BG$ is connected) to show that $\ev_{yy}$ is an equivalence. The composite

$$\ev_{yy} X : (y \xrightarrow{\sim} y) \rightarrow X_y y$$

is determined by $\ev_{yy} X(\text{refl}_y) \equiv pt_y$. By transitivity of $X_y$ this composite is surjective, hence $\ev_{yy}$ is surjective too.

On the other hand, in Lemma 4.7.14 we used the transitivity of $X_y$ to deduce that $\ev_{yy}$ was injective. Consequently $\ev_{yy}$ is an equivalence. But since $\ev_{yy}$ is an equivalence and $\ev_{yy} X$ is surjective we conclude that $X$ is surjective \(\square\)

**Definition 5.5.8.** Let $N : \nor_G$ be a normal subgroup with $N(y) \equiv (X_y, pt_y, !)$ for $y : BG$. The quotient group is

$$G/N \equiv \text{Aut}_{G-\text{Set}}(X_{sh_G}).$$

The quotient homomorphism is the homomorphism $q_N : \text{Hom}(G, G/N)$ defined by $Bq_N(z) \xrightarrow{\sim} X_z$ (strictly pointed). By Lemma 5.5.7, $q_N$ is an epimorphism and we have defined a map

$$q : \nor_G \rightarrow \text{Epi}_G, \quad q(N) \equiv (G/N, q_N, !).$$

**Remark 5.5.9.** It is instructive to see how the quotient homomorphism $Bq_N : BG \rightarrow BG/N$ is defined in the torsor interpretation of $BG$. If $Y : BG \rightarrow U$ is a $G$-type we can define the quotient as

$$Y/N : BG \rightarrow U, \quad Y/N(y) \equiv \sum_{z : BG} Y(z) \times X_z(y).$$
We note that in the case \( \text{Pr}_G(y) \equiv (\text{sh}_G \to y) \) we get that \( \text{Pr}_G/N(y) \equiv \sum_z:BG(\text{sh}_G \to z) \times X_z(y) \) is equivalent to \( X_{sh_c} \). Consequently, if \( Y \) is a \( G \)-torsor, then \( Y/N \) is in the component of \( X_{sh_c} \) and we have

\[-/N : \text{Torsor}_G \equiv (G\text{-set})_{\text{Pr}_G} \rightarrow (G\text{-set})_{X_{sh_c}}.\]

Our quotient homomorphism \( q_N : \text{Hom}(G, G/N) \) is the composite of the equivalence \( \text{P}^C : BG \to \text{Torsor}_G \) of Theorem 4.8.6 and the quotient map \(-/N\).

**Lemma 5.5.10.** The map \( \text{nor} : \text{Epi}_G \rightarrow \text{Nor}_G \) is an equivalence with inverse \( \text{q} : \text{Nor}_G \rightarrow \text{Epi}_G. \)

**Proof.** Assume \( N : \text{Nor}_G \) with \( N(y) \equiv (X_y, \text{pt}_y, !) \) for \( y : BG \). Then \( \text{nor} q(N) : BG \rightarrow \text{Set} \) takes \( y : BG \) to \( (\text{nor} q(N))(y) \equiv (Y_y, \text{refl}_{X_y} !) \), where \( Y_y(z) \equiv (X_y \to z) \). Noting that the equivalence \( \text{ev}_{Y_z} : (X_y \to z) \to X_z(y) \) of Lemma 5.5.7 has \( \text{ev}_{Y_z}(\text{refl}_{X_y}) \equiv \text{pt}_y \) we see that univalence gives us the desired identity \( \text{nor} q(N) \rightarrow N. \)

Conversely, let \( f : \text{Hom}(G, G') \) be an epimorphism. Recall that the quotient group is \( \text{G}/\text{nor}(f) \equiv \text{Aut}_G(\text{P}(\text{sh}_c)f) \) and the quotient homomorphism \( q_{\text{nor} f} : \text{Hom}(G, G/\text{nor} f) \) is given by sending \( y : BG \) to \( \text{P}(f y) : BG \to \text{Set} \) (strictly pointed – i.e., by \( \text{refl}_{\text{P}(\text{sh}_c)f} \)). We define a homomorphism \( Q : \text{Hom}(G', G/\text{nor} f) \) by sending \( z : BG' \) to \( \text{P}_z f \) and using the identification \( \text{P}_{\text{sh}_c} f \to f(\text{sh}_c) \) induced by \( \text{p} f : \text{sh}_c' \to f(\text{sh}_c) \) and notice the equality by definition:

\[ Q f \equiv q_{\text{nor} f} : \text{Hom}(G, G/\text{nor} f). \]

We are done if we can show that \( Q \) is an isomorphism. The preimage of the base point \( \text{P}(\text{sh}_c)f \) is

\[ \sum_z:BG' \prod_y:BG (z \equiv f(y)) \equiv (f(\text{sh}_c) \equiv f(y)) \]

which by Lemma 4.13.4 is equivalent to

\[ \sum_z:BG' \prod_v:BG (z \equiv v) \equiv (f(\text{sh}_c) \equiv v) \]

which by Lemma 4.8.5 is equivalent to the contractible type \( \sum_z:BG' z \equiv f(\text{sh}_c) \). \( \square \)

**Corollary 5.5.11.** *The kernel \( \ker : \text{Epi}_G \rightarrow \text{Ker}_G \) is an equivalence of sets.*

**Proof.** Since \( \text{nor} : \text{Epi}_G \rightarrow \text{Nor}_G \) and \( E : \text{Mono}_G \rightarrow \text{Sub}_G \) are equivalences, the inclusion of fixed points \( i : \text{Nor} \rightarrow \text{Sub} \) is an injection and the diagram in Lemma 5.5.6 commutes, the surjection \( \text{Epi}_G \rightarrow \text{Ker}_G \) is also an injection. \( \square \)

Summing up, using the various interpretations of subgroups, we get the following list of equivalent sets all interpreting what a normal subgroup is.

**Lemma 5.5.12.** Let \( G \) be a group, then the following sets are equivalent

1. The set \( \text{Epi}_G \) of epimorphisms from \( G \),
2. the set \( \text{Ker}_G \) of kernels of epimorphisms from \( G \),
(3) the set $\text{Nor}_G$ of fixed points of the $G$-set $\text{Sub}_G$ (aka. normal subgroups),
(4) the set of fixed points of the $G$-set $\text{Mono}_G$, 
(5) the set of fixed points of the $G$-set of abstract subgroups of $\text{abs}(G)$ of Lemma 5.4.4.

5.5.13 The associated kernel

With this much effort in proving that different perspectives on the concept of “normal subgroups” (in particular, kernels and fixed points) are the same, it can be worthwhile to make the composite equivalence

$$\ker q : \text{Nor}_G \xrightarrow{\sim} \text{Ker}_G$$

explicit – where the quotient group function $q : \text{Nor}_G \to \text{Epi}_G$ is the inverse of nor constructed in Definition 5.5.8 – and even write out a simplification.

Let $N : \text{Nor}_G$ be a normal subgroup with $N(y) \equiv (X_y, \text{pt}_y, !)$ for $y : BG$ with $X_y : BG \to \text{Set}$, $\text{pt}_y : X_y(y)$ and $! : \text{Trans}(X_y)$. Then

$$\text{Ker} q(N) \equiv \text{Aut}_{\sum x : BG(X_x \to X_{\text{sh}_G})}(\text{sh}_G, \text{refl}_{X_{\text{sh}_G}})$$

and with the monomorphism $i_{\text{ker} q(N)} : \text{Hom}(\text{Ker} q(N), G)$ given by the first projection from $\sum x : BG(X_x \to X_{\text{sh}_G})$ to $BG$.

However, going the other way around the pentagon of Lemma 5.5.6, we see that $\text{ass}(N) \equiv E^{-1}i(N) : \text{Mono}_G$ consists of the group

$$\text{Ass}(N) \equiv \text{Aut}_{\sum x : BG X_{\text{sh}_G}}(\text{sh}_G, \text{pt}_{\text{sh}_G})$$

and the monomorphism into $G$ given by the first projection (monomorphism because $X_{\text{sh}_G}$ has values in sets). Since the pentagon commutes we know that $\text{ass}(N)$ is the kernel of $q(N) : \text{Epi}_G$, and the identification $ev : i_{\text{ker} q(N)} \Rightarrow \text{Mono}_G \text{ass}(N)$ is given via Lemma 5.5.7 and univalence by the equivalence

$$ev_{X_{\text{sh}_G}} : (X_x \xrightarrow{=} X_{\text{sh}_G}) \to X_{\text{sh}_G}(x).$$

Letting the proposition that $\text{ass}(N)$ is a kernel be invisible in the notation we may summarize the above as follows:

**Definition 5.5.14.** If $N : \text{Nor}_G$ is a normal subgroup we call the kernel $\text{ass}(N) : \text{Ker}_G$ the kernel associated to $N$.

**Lemma 5.5.16.** The diagram of equivalences

![Diagram](https://example.com/diagram.png)

commutes.

**Remark 5.5.15.** In forming the kernel associated to $N$, where did we use that $N$ was a fixed point of the $G$-set $\text{Sub}_G$? If $Y : BG \to \text{Set}$ is a transitive $G$-set and $pt : Y(\text{sh}_G)$, then surely we could consider the group

$$W \equiv \text{Aut}_Y : BG \to \text{Set}(Y)$$

as a substitute for the quotient group (see Section 5.8). One problem is that we wouldn’t know how to construct a homomorphism from $G$ to $W$ which we then could consider the kernel of. And even if we tried our hand inventing formulas for the outcomes, ignoring all subscripts, we’d be stuck at the very end where we used Lemma 5.5.7 to show that the evaluation map is an equivalence; if we only had transitivity we could try to use a variant of Lemma 4.7.14 to pin down injectivity, but surjectivity needs the extra induction freedom.
5.6 Intersecting with normal subgroups

In Section 4.15 we defined the intersection of two monomorphisms and by extension, of two subgroups. This is particularly interesting when one of them is represented by a normal subgroup.

Exercise 5.6.1. If $G$ is an abstract group and $H$ and $K$ are abstract subgroups. Give a definition of the intersection $H \cap K$ is the abstract subgroup of $G$ agreeing with our definition for monomorphisms as in Definition 4.15.7.

Lemma 5.6.2. Let $(G', f, !) : \text{Epi}_G$ be an epimorphism, let $N$ be the kernel of $f$ and let $(H, i, !) : \text{Mono}_G$. Then $N \cap H$ is the kernel of $fi : \text{Hom}(H, G')$. and the induced homomorphism in $\text{Hom}(H/(N \cap H), G')$ is a monomorphism.

Proof. Now, $N$ is the kernel of the epimorphism $f$, giving an equivalence between $BN$ and the preimage

$$(Bf)^{-1}(\text{sh}_{G'}) := \sum_{y : BG} (\text{sh}_{G'} \xrightarrow{y} Bf(y)).$$

Writing out the definition of the pullback (and using that for each $x : BH$ the type $\sum_{y : BG} y \xrightarrow{y} Bi(x)$ is contractible), we get an equivalence between $BN \times_{BG} BH$ and

$$B(fi)^{-1}(\text{sh}_{G'}) := \sum_{x : BH} \text{sh}_{G'} \xrightarrow{x} B(f)i x,$$

the preimage of $\text{sh}_{G'}$ of the composite $B(fi) : BH \to BG'$. By definition, the intersection $B(N \cap H)$ is the pointed component of the pullback containing $(\text{pt}_N, \text{sh}_H)$. Under the equivalence with $B(fi)^{-1}(\text{sh}_{G'})$ the intersection corresponds to the component of $(\text{sh}_H, Bf(p_i) p_f)$. Since (by definition of the composite of pointed maps) $p_{fi} := Bf(p_i) p_f$, we get that the intersection $N \cap H$ is identified with the kernel of the composite $fi : \text{Hom}(H, G')$.

Finally, since $N \cap H$ is the kernel of the composite $fi : \text{Hom}(H, G')$, under the equivalence of Lemma 5.3.16, $N \cap H$ is equivalent to the kernel of the epimorphism $\text{pr}_{\text{im}(fi)} : \text{Hom}(H, \text{im}(fi))$. Otherwise said, the quotient group $H/(N \cap H)$ is another name for the image $\text{im}(fi)$, and $\text{in}_{\text{im}(fi)}$ is indeed a monomorphism into $G'$.

Exercise 5.6.3. Write out all the above in terms of the set $\text{Sub}_G$ of subgroups of $G$ instead of in terms of the set $\text{Mono}_G$ of monomorphisms into $G$.

Is the below misplaced?

Recall that if $X : BG \to \text{Set}$ is a $G$-set, then the set of fixed points is the set $\prod_{v : BG} X(v)$, which is a subset of $X(\text{sh}_G)$ via the evaluation map. If a homomorphism from a group $H$ to $G$ is given by $F : BH \to BG$, and $p_F : \text{sh}_G \xrightarrow{\pi} F(\text{sh}_H)$, then precomposition (“restriction of scalars”) by $F$ gives an $H$-set

$$F^* X \equiv \prod_{v : BH} XF(v).$$

In the case of inclusions of subgroups (or other situations where the homomorphism is clear from the context) it is not uncommon to talk about “the $H$-set $X$” rather than “$F^* X$”. This can be somewhat confusing when it comes to fixed points: the fixed points of $F^* X$ are given by $\prod_{v : BH} XF(v)$.
which evaluates nicely to \(X(F(sh_H))\), but in order to considered these as elements in \(X(sh_G)\) we need to apply \(X(p_F^{-1}) : X(F(sh_H)) \xrightarrow{\sim} X(sh_G)\).

Consequently, we’ll say that \(x : X(sh_G)\) is an \(H\)-fixed point if there is an \(f : \prod_{v : BG} XF(v)\) such that \(x \xrightarrow{\sim} X(p_F^{-1})f(sh_H)\).

**Lemma 5.6.4.** Let \(G\) be a group, \(X : BG \to \text{Set}\) a \(G\)-set, \(x : X(sh_G)\), \(g : UG\) and \(H \xrightarrow{\sim} (H, F, p, !) : \text{Sub}_G\) a subgroup of \(G\) (\(F : BH \to BG\) and \(p : sh_G \xrightarrow{\sim} F(sh_H)\)).

Then \(g \cdot x\) is a fixed point for the \(H\)-action on \(X\) if and only if \(x\) is a fixed point for the action of the conjugate subgroup \(gH \equiv (H, F, g^{-1}pF, !)\) on \(X\).

**Proof.** Consider an \(f : \prod_{v : BH} XF(v)\). Then \(g \cdot x \xrightarrow{\sim} X(p_F^{-1})(f(sh_H))\) if and only if \(x \xrightarrow{\sim} g^{-1} \cdot X(p_F^{-1})(f(sh_H)) \equiv X((g^{-1}pF)^{-1}(f(sh_H)))\). \(\square\)

### 5.7 Automorphisms of groups

Most of this intro including Rem. 5.7.1 has been copied to the end of Section 4.4, but a short recap is of course never wrong. This section explores the relation between the symmetries in a group \(G\), and the symmetry of the group \(G\). More formally, recall that Group is a groupoid, hence \(\text{Aut}_{\text{Group}}(G)\) is defining a group, that we will simply denote \(\text{Aut}(G)\) in the rest of this section. Recall in particular that \(\text{BAut}(G)\) is the connected component of \(G\) in type of groups (pointed at \(G\), which is equivalent to the connected component of \(BG\) in \(\mathcal{U}\), (pointed at \(BG\)). Let us now use this equivalence to define an homomorphism \(\text{inn} : G \to \text{Aut}(G)\) by setting

\[
\text{inn} : BG \to \text{BAut}(G), \quad y \mapsto \Omega(BG, y)
\]

where the path pointing \(\text{inn}\) is \(p_{\text{inn}} \equiv \text{refl}_G : G \xrightarrow{\sim} \text{Binn}(sh_G)\). Notice that for this map \(\text{inn}\) to be defined properly, we need to show that, for all \(y : BG\), the proposition \(\|G \xrightarrow{\sim} \Omega((BG, y))\|\) holds. **Easy with Example 4.4.26** We are targeting a family of propositions from the connected type \(BG\), so it is enough to prove the proposition at \(y \equiv sh_G\), for which it is obvious: take \([\text{refl}_G]\) as an element of \(\|G \xrightarrow{\sim} \Omega(BG, sh_G)\|\).

**Remark 5.7.1.** For pedagogical purposes, we will now make explicit the map

\[
\text{inn} : UG \to U(\text{Aut}(G)).
\]

More precisely, for each symmetry \(g : UG\), the element \(U\text{inn}(g)\) is a symmetry of \(\text{Aut}(G)\), that is, through univalence, a isomorphism of groups from \(G\) to itself. We want to describe the automorphism \(U\text{inn}(g)\). By definition, **(Easier with Example 4.4.26)** \(U\text{inn} \equiv \text{refl}_G^{-1} \cdot \text{ap}_{\text{Binn}(\_)} \cdot \text{refl}_G\). So it remains to determine \(\text{ap}_{\text{Binn}}\). We proceed by induction on \(p : sh_G \xrightarrow{\sim} y\) to prove that \(B(\text{ap}_{\text{Binn}}(p))\) is equal to the path in \(BG \xrightarrow{\sim} (BG, y)\) given by the pair of paths \((\text{refl}_{BG}, p)\) \(-\text{indeed, this is trivial for } p \equiv \text{refl}_{sh_G}\). Then, through univalence, \(\text{Binn}(p)\) is the equivalence \(\text{id}_{BG}\), pointed by the path \(p\). In particular, when \(p : UG\) is a symmetry in \(G\), then \(B(U\text{inn}(g))\) is the equivalence in \(BG \xrightarrow{\sim} BG\) given by \(\text{id}_{BG}\), pointed by \(g\). Or in terms of abstract groups:

\[
U(U\text{inn}(g)) : UG \xrightarrow{\sim} UG, \quad h \mapsto g^{-1}hg
\]
In that form, it is easier for the reader that is used to group theory in set-theoretic foundations to see that the homomorphism \( \text{inn} \) is taking each elements of the group to the inner automorphism associated to it.

After the interlude in the remark, it should come as no surprise that we can identify the kernel of \( \text{inn} \) with the center of \( G \). Indeed, there is a composition of identifications from the fiber at \( G' : \text{BAut}(G) \) of Binn as follows:

\[
\text{(Binn)}^{-1}(G') \equiv \left( \sum_{y : \text{BG}} G' \xrightarrow{\sim} \Omega((\text{BG}_-, y)) \right)
\xrightarrow{\sim} \left( \sum_{y : \text{BG}, p : \text{BG}_-} y \xrightarrow{\sim} \text{trp}_p(\text{sh}_{G'}) \right)
\xrightarrow{\sim} (\text{BG}_- \xrightarrow{\sim} \text{BG}_-)
\]

In particular, we can consider the equivalence from the fiber at \( \text{sh}_{\text{Aut}(G)} \equiv \text{G} \) to \( \text{BG}_- \xrightarrow{\sim} \text{BG}_- \). Through this equivalence, the point \( (\text{sh}_G, \text{Binn}) \) is transported to \( \text{refl}_{\text{BG}_-} \). Hence, we have an identification in

\[
\text{Ker}(\text{inn}) \equiv \text{Aut}(\text{Binn})^{-1}(\text{G})(\text{sh}_G, \text{refl}_{\text{BG}}) \xrightarrow{\sim} \text{Aut}(\text{BG}_- \xrightarrow{\sim} \text{BG}_-)(\text{refl}_{\text{BG}}) \xrightarrow{\sim} Z(G).
\]

Under this equivalence, the associated map \( \text{in}_{\text{ker}(\text{inn})} \) becomes the homomorphism \( z_G \) described in Section 4.12.

**Definition 5.7.2.** The \( \text{Aut}(G) \)-set of outer automorphism, denoted \( \text{out}(G) \), is the cokernel of \( \text{inn} \).

**Lemma 5.7.3.** The \( \text{Aut}(G) \)-set \( \text{out}(G) \) can be identified with

\[
\text{Aut}(G) \rightarrow \text{Set}, \quad G' \mapsto \|BG'_- \xrightarrow{\sim} \text{BG}_-\|_0
\]

**Proof.** Simply recall the computation of the fibers of Binn above. Then, for each \( G' : \text{BAut}(G) \), we have an element of

\[
\text{out}(G)(G') \equiv \|\text{(Binn)}^{-1}(G')\|_0 \xrightarrow{\sim} \|BG'_- \xrightarrow{\sim} \text{BG}_-\|_0
\]

\( \square \)

**Definition 5.7.4.** The group \( \text{Inn}(G) \) of inner morphisms of \( G \) is the image \( \text{Im}(\text{inn}) \) of \( \text{inn} \).

Notice that, the classifying type \( B \text{Im} \text{(inn)} \) being the total type of the cokernel of \( \text{inn} \), the above identification of \( \text{out}(G) \) provides us with an equivalence in

\[
B \text{Inn}(G) \xrightarrow{\sim} \left( \sum_{G' : \text{Group}} \|BG'_- \xrightarrow{\sim} \text{BG}_-\|_0 \right)
\]

**Lemma 5.7.5.** The group \( \text{Inn}(G) \) is normal when seen as a subgroup of \( \text{Aut}(G) \).

**Proof.** The precise meaning of the statement is that there exists a dependent function \( N : \prod_{G' : \text{Aut}(G)} \text{Sub}_{\text{Aut}(G)}(G') \) and a path in \( N(\text{sh}_{\text{Aut}(G)}) \xrightarrow{\sim} E(\text{im}(\text{inn})) \). Expanding the definition of \( \text{Sub}_{\text{Aut}(G)} \), our task in defining \( N \) is to find for every \( G' \) a transitive \( \text{Aut}(G) \)-set \( X \) together with a point of \( X(G') \). We suggest to define \( N(G') \) to be the transitive \( \text{Aut}(G) \)-set

\[
X : \text{Aut}(G) \rightarrow \text{Set}, \quad H \mapsto \|BG'_- \xrightarrow{\sim} BH_+\|_0
\]
together with the point \(|\text{refl}_{BG}|_0 : X(G')\).

Let us prove that \(N(\text{sh}_{\text{Aut}(G)})\) can be identified with the subgroup \(E(\text{im}(\text{inn}))\). First notice that \(\text{sh}_{\text{Aut}(G)} \equiv G\) and that \(E(\text{im}(\text{inn})) \equiv (\text{out}(G), |G, \text{refl}_{BG}|_0)\).

For simplicity, write \(X_G\) for the first component \(N(G)\) and \(x_G : X_G(G)\) for its second component. Lemma 5.7.3 provides us with a path \(p : \text{out}(G) \xrightarrow{\sim} X_G\). Checking that \(\text{trp}_p((G, \text{refl}_{BG}|_0)\) can be identified with \(|\text{refl}_{BG}|_0\) is just a matter of looking at the equivalence exhibited in Lemma 5.7.3.

To be thorough, we actually need to prove that the first component of each \(N(G')\) (denoted \(X\) above) is transitive: being transitive is a proposition and by connectedness of \(\text{Aut}(G)\), it suffices to prove it when \(G' \equiv G\), for which the first component of \(N(G')\) has been identified with \(\text{out}(G)\); however, \(\text{out}(G)\), as a cokernel, is known to be transitive. \(\square\)

We make the abuse of denoting \(\text{Inn}(G)\) for the normal subgroup of \(\text{Aut}(G)\) defined by \(\text{Inn}(G)\) as specified above.

**Definition 5.7.6.** The group of *outer automorphisms* of \(G\), denoted \(\text{Out}(G)\), is the group

\[
\text{Out}(G) \equiv \text{Aut}(G) / \text{Inn}(G) \equiv \text{Aut}_{\text{Aut}(G)-\text{Set}}(\text{out}(G))
\]

**Construction 5.7.7.** There is an identification of groups

\[
\Phi : \text{Aut}_{\|\mathcal{U}\|_1}(\|BG|_1) \xrightarrow{\sim} \text{Out}(G)
\]

Before going through the construction of \(\Phi\), let us describe its domain in more details. The goal of this construction is to have a alternative version of \(\text{Out}(G)\) with a more tractable classifying type. Because \(\text{out}(G)\) is a transitive \(\text{Aut}(G)\)-set, and because the associated subgroup is normal, then its type of symmetries should be equivalent to \(\text{out}(G)\)(\(G\)), which we know can be identified with \(\|BG| \rightarrow BG\|_0\). The idea is then to find a pointed groupoid for which the loop space is readily \(\|BG| \rightarrow BG\|_0\).

However, \(|a \xrightarrow{\sim}_A b|_0\) is equivalent to \(|a|_1 \xrightarrow{\sim}_{\|\mathcal{U}\|_1} |b|_1\) for any element \(a\) and \(b\) of type \(A\). Hence it becomes natural to try to establish an equivalence between \(\text{Out}(G)\) and the group of symmetries of \(|BG|_1\) in the groupoid \(\|\mathcal{U}\|_1\).

**Implementation of Construction 5.7.7.** Notice that the function \(|\cdot|_1 : \mathcal{U} \rightarrow \|\mathcal{U}\|_1\) induces an isomorphism on connected components: indeed, \(|X|_1 = |Y|_1\) if and only if \(\|\|X \rightarrow Y\||_0\) if and only if \(X = Y\). In other words, \(\text{BAut}_{\|\mathcal{U}\|_1}(\|BG|_1)\) identifies with the 1-truncation of \(\|\mathcal{U}\|_1\).

As \(\text{BOut}(G)\) is a groupoid, every map \(\text{BAut}_{\|\mathcal{U}\|_1}(\|BG|_1) \rightarrow \text{BOut}(G)\) is induced by a map \(\mathcal{U}_{(BG)} \rightarrow \text{BOut}(G)\). Thus we define \(\Phi\) by setting the pointed map \(B\Phi\) to be the map induced by:

\[
\varphi : \left(\sum_{X : \mathcal{U}} BG = X\right) \rightarrow \text{BOut}(G)
\]

\[(X, \omega) \mapsto \{\text{BAut}(G) \rightarrow \text{Set}, G' \mapsto \|BG' \rightarrow X\|_0\}\]

This map is well defined: given \((X, \omega)\) is the domain, we are trying to prove the proposition \(\text{out}(G) \xrightarrow{\varphi(X, \omega)} \omega\), so we can lift the propositional truncation of \(\omega\) and assume that we have \(w : BG \rightarrow X\). Then, we craft

Here, \(|w|_0\) is not the element represented by \(w\) in \(\|BG| \rightarrow X\|_0\), but in fact the equivalence \(\|BG\|_0 \rightarrow \|X\|_0\) induced by \(w\).
an identification of type \( \text{out}(G) \to \phi(X, \omega) \) by noticing that we have for every \( G' : B\text{Aut}(G) \) an identification

\[
[\omega]_0 \circ \_ : \|BG' \| \to \|BG' \| \longrightarrow \|BG' \| \to X_0
\]

We no proceed to prove that \( B\Phi \) is an equivalence, to conclude that \( \Phi \) is an isomorphism of groups. As both the domain and codomain of \( B\Phi \) are connected, to prove that it is an equivalence, it is enough to show that \( \text{ap}_{B\Phi} : (a \to a) \to (B\phi a \to B\phi a) \) for a chosen \( a \) in the domain. We consider of course \( a \equiv ([BG.]_1, \text{refl}_{[BG.]_1}) \). Then,

\[
B\Phi(a) \equiv \phi(BG., \text{refl}_{BG.}) \equiv (G' \to [BG']_1 \to BG.\|_0)
\]

By path induction, one can show that for each \( p : [BG.]_1 \to [BG.]_1 \), we get paths of type

\[
\text{ap}_{B\Phi}(p) \to \{ G' \to \hat{\rho} \circ \_ \}
\]

where \( \_ \) is the equivalence \( ([x]_1 \to [y]_1) \to [x] \to [y]_0 \).

Because the subgroup associated with \( \text{out}(G) \) is normal, Lemma 5.5.7 provides us with an equivalence \( \text{ev} : (\text{out}(G) \to \text{out}(G)) \to \text{out}(G)(G) \).

Write \( \psi \) for the path out \( G \to G' \to [BG']_1 \to BG.\|_0 \) of Lemma 5.7.3. Then, for every \( p : [BG.]_1 \to [BG.]_1 \), one get an identification

\[
\psi_G \left( \text{ev} \left( \psi^{-1} \cdot \text{ap}_{B\Phi}(p) \cdot \psi \right) \right) \to \hat{\rho}
\]

Hence, composition of \( \text{ap}_{B\Phi} \) with equivalences is an equivalence, proving that \( \text{ap}_{B\Phi} \) itself is an equivalence.

\( \square \)

5.8 The Weyl group

In Definition 5.5.8 defined the quotient group of a normal subgroup. As commented in Definition 5.5.14, the definition itself never used that the subgroup was normal (but the quotient homomorphism did) and is important in this more general context.

Recall the equivalence \( E \) between the set \( \text{Mono}_G \) of monomorphisms and the set \( \text{Sub}_G \) of of subgroups of \( G \) (pointed transitive \( G \)-sets): The subgroup \((X, \text{pt}_X, !) : \text{Sub}_G \) where \( X : BG \to \text{Set} \) is a transitive \( G \)-set and \( \text{pt}_X : X(\text{sh}_G) \) corresponds to \((H, i_H, !) : \text{Mono}_G \) defined by

\[
H : = \text{Aut}_{\sum_{y : BG} X(y)}(\text{sh}_G, \text{pt}_X)
\]

together with the first projection from \( \sum_{y : BG} X(y) \) to \( BG \). Conversely, if \((H, i_H, !) : \text{Mono}_G \), then the corresponding transitive \( G \)-set is \( G/H \equiv \text{coker} \ i_H \) pointed at \( \text{sh}_{i_H} \cdot p_{i_H} : \text{coker} \ i_H(\text{sh}_G) \equiv \sum_{x : BH} \text{sh}_G \to B(i_H(x))\|_0 \).

For the remainder of the section we’ll consider a fixed group \( G \), monomorphism \( i_H : \text{Hom}(H, G) \) and \((X, \text{pt}_X, !) \) will be the associated pointed transitive \( G \)-set.

Definition 5.8.1. The Weyl group

\[
W_G : H \equiv \text{Aut}_{\text{Set}}(X)
\]

is defined by the component \( BW_G \) of the groupoid of \( G \)-sets pointed at \( X \).

The normalizer subgroup

\[
N_G : H \equiv \text{Aut}_{\sum_{y : \text{Sub}_G} \text{Sub}_G(y)}(\text{sh}_G, X, \text{pt}_X)
\]
is defined by the component $B_N G H$ of the groupoid $\sum_{y: BG} \text{Sub}_C(y)$ pointed at $(\text{sh}_G, X, \text{pt}_X)$. Unpacking, we find that

$$BN_G H \Delta \equiv \sum_{y: BG} \sum_{y: \text{Set}} \sum_{y: X(y)} \|(\text{sh}_G, X, \text{pt}_X) \to (y, Y, \text{pt}_Y^y)\|.$$  

While the projection $((\text{sh}_G, X, \text{pt}_X) \to (y, Y, \text{pt}_Y^y)) \to (X \to Y)$ may not be an equivalence, the transitivity of $X$ tells us that for any $\beta: X \to Y$ there is a $g: \text{sh}_G \to y$ such that $X(g) \to Y \to \beta^{-1} \text{pt}_X$, and so the propositional truncation $\|(\text{sh}_G, X, \text{pt}_X) \to (y, Y, \text{pt}_Y^y)\| \to ||X \to Y||$ is an equivalence. Consequently, the projection

$$BN_G H \Delta \to \sum_{y: BG} \sum_{y: \text{Set}} \sum_{y: X(y)}\|X \to Y\|$$

is an equivalence. With an innocent rewriting, we see that we have provided an equivalence

$$e : BN_G H \Delta \iso \sum_{(y:Y): \text{BG} \times BW_G H} Y(y) \quad e(y, Y, \text{pt}_Y^y, !) \equiv (y, Y, \text{pt}_Y^y, !).$$

This formulation has the benefit of simplifying the analysis of the monomorphism

$$i_{N_G H} : \text{Hom}(N_G H, G)$$

given by $B_{i_{N_G H}}(y, Y, \text{pt}_Y^y, !) \equiv y$, the “projection”

$$p_G^H : \text{Hom}(N_G H, W_G H)$$

and $B_{p_G^H}(y, Y, \text{pt}_Y^y, !) \equiv (Y, !)$ and the monomorphism

$$j_{i_H} : \text{Hom}(H, N_G H)$$

given by $B_{j_{i_H}}(y, v) \equiv (y, X, v, !)$.

**Lemma 5.8.2.** The monomorphism $i_{G}^H : \text{Hom}(N_G H, G)$ displays the normalizer as a subgroup of $G$ and the projection $p_G^H : \text{Hom}(N_G H, W_G H)$ is an epimorphism.

The homomorphism $j_{i_H} : \text{Hom}(H, N_G H)$ defines $H$ as a normal subgroup of the normalizer,

$$\ker p_G^H \iso \text{Mon}_{G;\text{for}}(H, i_{i_H}, !)$$

and $i_{i_H} \iso \text{Hom}(H, G)^H_{G; j_{i_H}}$.

**Proof.** Immediate from (our rewriting of) the definitions. □

The Weyl group $W_G H$ has an important interpretation. It is defined as symmetries of the transitive $G$-set $X$, and so $\text{pt}_W G_H \iso \text{pt}_W G_H$ is nothing but $(X \iso \text{G-set} X) \iso \prod_{y: BG} (X(y) \iso X(y))$. On the other hand, $BH_\Delta$ is equivalent to $\sum_{y: BG} X(y)$ and

$$\prod_{y: BG} (X(y) \iso X(y)) \iso \prod_{y: \text{BG}} X(y),$$

so $\text{pt}_W G_H \iso \text{pt}_W G_H$ is equivalent to the set $\prod_{x: BH} X(\text{Bi}_H x)$ of fixed points of $X \iso G/H$ (regarded as an $H$-set through $i_{i_H}$).

Summing up

**Lemma 5.8.3.** The map $e : (X \iso X) \to \prod_{x: BH} X(\text{Bi}_H x)$ with $e(f)(y, v) \iso f(y)$ defines an equivalence

$$e : (\text{pt}_W G_H \iso \text{pt}_W G_H) \iso (G/H)^H.$$
5.9 The orbit-stabilizer theorem

Let $G$ be a group (or $\infty$-group) and $X : BG \to U$ a $G$-type. Recall the orbit type of Definition 4.7.19 $X_{hG} \equiv \sum_{z : BG} X(z)$ and its truncation, the set of orbits $X/G \equiv ||X_{hG}||_0$ and the map $X(sh_G) \to X_{hG}$ sending $x : X(sh_G)$ to $[x] \equiv (sh_G, x)$.

For an element $x : X(sh_G)$ consider the associated subtype of $X(sh_G)$ consisting of all $y : X(sh_G)$ so that $[[y]]$ is equal to $x$ in the set of orbits:

$$O_x \equiv \sum_{y : X(sh_G)} x =_{X/G} [[y]].$$

For a point $x : X(sh_G)$, we call $G \cdot x \equiv O_{[[x]]}$ the orbit through $x$. Note the (perhaps) unfortunate terminology: an "orbit" is not an element in the orbit type, but rather consists of all the elements in $X(sh_G)$ sent to a given element in the orbit set.

In this way, the (abstract) $G$-type $X(sh_G)$ splits as a disjoint union (i.e., a $\Sigma$-type over a set) of orbits, parametrized by the set of orbits:

**Lemma 5.9.1.** The inclusions of the orbits induce an equivalence

$$\sum_{z : X/G} O_z \to X(sh_G).$$

The stabilizer group (also known as the isotropy group) of $x : X(sh_G)$ is the automorphism group of $[x]$ in the orbit type

$$G_x \equiv \text{Aut}_{X_{hG}}([x]),$$

so that $X_{hG}$ is equivalent to the disjoint union $\sum_{z : X/G} (BG_z)$. For $x : X(sh_G)$ the restriction of the first projection $\text{fst} : X_{hG} \to BG$ to the component of $[x]$ gives a homomorphism $i_x : \text{Hom}(G_x, G)$ if we point it by $\text{refl}_{sh_G} : sh_G = \text{fst}([x])$.

Recall that if $H$ and $G$ are groups, the set of homomorphisms $	ext{hom}(H, G)$ is a $G$-set. In particular, if $g : sh_G = sh_G$ and $f : \text{hom}(H, G)$, then we can denote the result of letting $g$ act on $f$ by $f^g : \text{hom}(H, G)$ which has $B(f^g) \equiv Bf$, but is pointed by $p \cdot g^{-1} : sh_G = Bf_{\cdot}(sh_H)$ (i.e., precomposing the witness $p \cdot : sh_G = f(sh_H)$ with the inverse of $g$). In the case where $f$ was a monomorphism so that it defines a subgroup, we called $f^g$ the conjugate of the original subgroup.

If $g : sh_G = sh_G$ the identity map of $X_{hG}$ can be pointed by the identity between $(sh_G, x)$ and $(sh_G, gx)$ given by $g : sh_G = sh_G$ and $\text{refl}_{gx}$ to give an isomorphism from $G_x$ to $G_{gx}$ identifying (by univalence) the homomorphism $i_{gx} : \text{hom}(G_{gx}, G)$ with $i_{x}^{-1} : \text{hom}(G_x, G)$.

In the case where $X$ is a $G$-set, the homomorphism $i_x : \text{hom}(G_x, G)$ is a monomorphism, and with this extra information we consider $G_x$ as a subgroup of $G$. Thus, different points in the same orbit of $X(sh_G)$ have conjugate stabilizer subgroups.

Another way of formulating these ideas is to consider the $G$-type

$$O_x : BG \to U, \quad O_x(z) \equiv \sum_{y : X(z)} [[[z]]] =_{X/G} ([z, y]),$$

and obtain the alternative definition of $BG_x$ as $\sum_{z : BG} O_x(z)$, which we see is a subgroup exactly when $O_x$ is a $G$-set.

We say that the action is **free** if all stabilizer groups are trivial.
**Theorem 5.9.2 (Orbit-stabilizer theorem).** Fix a $G$-type $X$ and a point $x : X(\text{sh}_G)$. There is a canonical action $\tilde{\mathcal{G}} : \text{BG}_x \to \mathcal{U}$, acting on $\tilde{\mathcal{G}}(\text{sh}_G) \simeq G$ with orbit type $\tilde{\mathcal{G}}_{h\mathcal{G}_x} \simeq O_x$.

**Proof.** Define $\tilde{\mathcal{G}}(x, y, !) : (\text{sh}_G = x)$.

Now suppose that $G$ is a 1-group acting on a set. We see that the orbit type is a set (and is thus equivalent to the set of orbits) if and only if all stabilizer groups are trivial, i.e., if and only if the action is free.

If $G$ is a 1-group, then so is each stabilizer-group, and in this case (of a set-action), the orbit-stabilizer theorem tells us that

**Theorem 5.9.3 (Lagrange’s Theorem).** If $H \to G$ is a subgroup, then $H$ has a natural action on $G$, and all the orbits under this action are equivalent.

**5.10 The isomorphism theorems**

Cf. Section 2.27

Group homomorphisms provide examples of forgetting stuff and structure. For example, the map from cyclically ordered sets with cardinality $n$ to the type of sets with cardinality $n$ forgets structure, and represents an injective group homomorphism from the cyclic group of order $n$ to the symmetric group $\Sigma_n$.

And the map from pairs of $n$-element sets to $n$-element sets that projects onto the first factor clearly forgets stuff, namely, the other component. It represents a surjective group homomorphism.

More formally, fix two groups $G$ and $H$, and consider a homomorphism $\varphi$ from $G$ to $H$, considered as a pointed map $B\varphi : \text{BG} \to \text{pt} BH$. Then $B\varphi$ factors as

$$
\text{BG} = \sum_{w : \text{BH}} \sum_{z : \text{BG}} (B\varphi(z) = w) \\
\to \text{pt} \sum_{w : \text{BH}} \sum_{z : \text{BG}} (B\varphi(z) = w) \\
\to \text{pt} \sum_{w : \text{BH}} \sum_{z : \text{BG}} (B\varphi(z) = w) = BH.
$$

The pointed, connected type in the middle represents a group that is called the image of $\varphi$, $\text{Im}(\varphi)$.

(FIXME: Quotient groups as automorphism groups, normal subgroups/normalizer, subgroup lattice)

**Lemma 5.10.1.** The automorphism group of the $G$-set $G/H$ is isomorphic to $\text{NC}_H(G)/H$.

**Theorem 5.10.2 (Fundamental Theorem of Homomorphisms).** For any homomorphism $f : \text{Hom}(G, G')$ the map TODO defines an isomorphism $G/\ker f \simeq \text{Im } f$.

**5.11 (the lemma that is not) Burnside’s lemma**

**Lemma 5.11.1.** Let $G$ be a finite group acting on a finite set $X$. Then the set of orbits is finite with cardinality

$$
\text{Card}(X/G) = \frac{1}{\text{Card}(G)} \sum_{g : \text{El} G} \text{Card}(X^g),
$$

insert that the action is free (referred to)

9TODO: Fix and move to Ch. 5
where \( X^g = \{ x : X \mid gx = x \} \) is the set of elements that are fixed by \( g \).

**Proof.** Since \( X \) and \( G \) is finite, we can decide equality of their elements. Hence each \( X^g \) is a finite set, and since \( G \) is finite, we can decide whether \( x, y \) are in the same orbit by searching for a \( g \in \text{El} G \) with \( gx = y \). Hence the set of orbits is a finite set as well.

Consider now the set \( R \equiv \sum_{g \in \text{El} G} X^g \), and the function \( q : R \to X \) defined by \( q(g, x) \equiv x \). The map \( g^{-1}(x) \to G_x \) that sends \( (g, x) \) to \( g \) is a bijection. Thus, we get the equivalences

\[
R \equiv \sum_{g \in \text{El} G} X^g \simeq \sum_{x : X} \sum_{z : O_z} G_x \simeq \sum_{X/G : O} z \sum_{x : O_z} G_x,
\]

where the last step writes \( X \) as a union of orbits. Within each orbit \( O_z \), the stabilizer groups are conjugate, and thus have the same finite cardinality, which from the orbit-stabilizer theorem (Theorem 5.9.2), is the cardinality of \( G \) divided by the cardinality of \( O_z \). We conclude that \( \text{Card}(R) = \text{Card}(X/G) \text{Card}(G) \), as desired. \( \Box \)

### 5.12 More about automorphisms

For every group \( G \) (which for the purposes of the discussion in this section we allow to be a higher group) we have the automorphism group \( \text{Aut}(G) \). This is of course the group of self-identifications \( G = G \) in the type of groups, \( \text{Group} \).

If we represent \( G \) by the pointed connected classifying type \( BG \), then \( \text{Aut}(G) \) is the type of pointed self-equivalences of \( BG \).

We have a natural forgetful map from groups to the type of connected groupoids. Define the type \( \text{Bunch} \) to be the type of all connected groupoid. If \( X : \text{Bunch} \), then all the elements of \( X \) are merely isomorphic, that is, they all look alike, so it makes sense to say that \( X \) consists of a bunch of alike objects.

For every group \( G \) we have a corresponding bunch, \( BG_\ldots \), i.e., the collection of \( G \)-torsors, and if we remember the basepoint \( sh_G : BG_\ldots \), then we recover the group \( G \). Thus, the type of groups equivalent to the type \( \sum X : \text{Bunch} \) of pairs of a bunch together with a chosen element. (This is essentially our definition of the type \( \text{Group} \).

Sometimes we want to emphasize that we \( BG_\ldots \) is a bunch, so we define \( \text{bunch}(G) \equiv BG_\ldots : \text{Bunch} \).

**Definition 5.12.1 (The center as an abelian group).** Let

\[
Z(G) \equiv \prod_{z : BG} (z = z)
\]

denote the type of fixed points of the adjoint action of \( G \) on itself. This type is equivalent to the automorphism group of the identity on \( \text{bunch}(G) \), and hence the loop type of

\[
\text{BZ}(G) \equiv \sum_{f : BG \to BG} \|f \sim \text{id}\|_{-1}.
\]

This type is itself the loop type of the pointed, connected type

\[
\text{B}^2Z(G) \equiv \sum_{X : \text{Bunch}} \|\text{bunch}(G) = X\|_0,
\]
and we use this to give \( Z(G) \) the structure of an abelian group, called the center of \( G \).

There is a canonical homomorphism from \( Z(G) \) to \( G \) given by the pointed map from \( BZ(G) \) to \( BG \) that evaluates at the point \( \text{sh}_G \). The fiber of the evaluation map \( e : BZ(G) \to \text{pt} BG \) is

\[
\text{fiber}_e(\text{sh}_G) \equiv \sum_{f : BG \to BG} \| f \sim \text{id}|_{-1} \times (f \text{sh}_G = \text{sh}_G)
\]

\[
\cong \sum_{f : BG \to \text{pt} BG} \| f \sim \text{id}|_{-1},
\]

and this type is the loop type of the pointed, connected type

\[
\text{B Inn}(G) \equiv \sum_{H : \text{Group}} \| \text{bunch}(G) = \text{bunch}(H)||_0,
\]

thus giving the homomorphism \( Z(G) \) to \( G \) a normal structure with quotient group \( \text{Inn}(G) \), called the inner automorphism group.

Note that there is a canonical homomorphism from \( \text{Inn}(G) \) to \( \text{Aut}(G) \) given by the pointed map \( i : B\text{Inn}(G) \to B\text{Aut}(G) \) that forgets the component. On loops, \( i \) gives the inclusion into \( \text{Aut}(G) \) of the subtype of automorphisms of \( G \) that become merely equal to the identity automorphism of \( \text{bunch}(G) \). The fiber of \( i \) is

\[
\text{fiber}_i(\text{sh}_G) \equiv \sum_{H : \text{Group}} \| \text{bunch}(G) = \text{bunch}(H)||_0 \times (H = G)
\]

\[
\cong \| \text{bunch}(G) = \text{bunch}(G)||_0.
\]

This is evidently the type of loops in the pointed, connected groupoid

\[
\text{B Out}(G) \equiv \| X : \text{Bunch} \| \text{bunch}(G) = X||_0,\]

thus giving the homomorphism \( \text{Inn}(G) \) to \( \text{Aut}(G) \) a normal structure with quotient group \( \text{Out}(G) \), called the outer automorphism group. Note that \( \text{Out}(G) \) is always a 1-group, and that it is the decategorification of \( \text{Aut(\text{bunch}(G))} \).

**Theorem 5.12.2.** Let two groups \( G \) and \( H \) be given. There is a canonical action of \( \text{Inn}(H) \) on the set of homomorphisms from \( G \) to \( H, \| BG \rightarrow \text{pt} BH||_0 \). This gives rise to an equivalence

\[
\| BG \rightarrow BH||_0 \cong \left( \| BG \rightarrow \text{pt} BH||_0 \right)_h \text{Inn}(H),
\]

between the set of maps from \( \text{bunch}(G) \) to \( \text{bunch}(H) \) and the set of components of the orbit type of this action.

**Proof.** We give the action by defining a type family \( X : B\text{Inn}(H) \to \mathcal{U} \) as follows

\[
X (K, \phi) \equiv \| \text{Hom}(G, K)||_0 \equiv \| BG \rightarrow \text{pt} BK||_0,
\]
for \((K, \phi) : \text{BInn}(H) \equiv \sum_{K : \text{Group}} \|\text{bunch}(H) = \text{bunch}(K)\|_0\). Now we can calculate

\[
\|X_{\text{Inn}(H)}\|_0 \equiv \left\| \sum_{K : \text{Group}} \|\text{bunch}(H) = \text{bunch}(K)\|_0 \times \|\text{Hom}(G, K)\| \right\|_0
\]

\[
\approx \left\| \sum_{K : \text{Group}} (\text{bunch}(H) = \text{bunch}(K)) \times \text{Hom}(G, K) \right\|_0
\]

\[
\approx \left\| \sum_{K : \text{Bunch}} \sum_k (\text{bunch}(H) = K) \times \sum_{f : \text{bunch}(G) \to K} f \text{ pt} = k \right\|_0
\]

\[
\approx \left\| \sum_{K : \text{Bunch}} (\text{bunch}(H) = K) \times (\text{bunch}(G) \to K) \right\|_0
\]

\[
\approx \|\text{bunch}(G) \to \text{bunch}(H)\|_0 \equiv \|BG_\cdot \to BH_\cdot\|_0. \tag*{\square}
\]
Finitely generated groups

| https://math.ucr.edu/home/baez/six.html Relating $\Sigma_6$ to the icosahedron. The icosahedron has 6 axes. Two axes determines a golden rectangle (also known as a \textit{duad},\footnote{These names come from Sylvester.} so there are 15 such. A symmetry of the icosahedron can be described by knowing where a fixed rectangle goes, and a symmetry of that rectangle. Picking three rectangles not sharing a diagonal gives a \textit{syntheme}: three golden rectangles whose vertices make up the icosahedron. Some synthemes (known as \textit{true crosses} have the rectangles orthogonal to each other, as in Fig. 6.1. Fact: The symmetries of the icosahedron form the alternating symmetries of the 5 true crosses. Of course, we get an action on the 6 axes, thus a homomorphism $A_5 \to \Sigma_6$. Every golden rectangle lies in one true cross and two skew crosses. The combinatorics of duads, synthemes, and synthematic totals are illustrated in the Cremona-Richardson configuration and the resulting Tutte-Coxeter graph. The automorphism group of the latter is in fact $\text{Aut}(\Sigma_6)$. If we color the vertices according to duad/syntheme, we get $\Sigma_6$ itself. |
| • define (left/right) presentation complex of group presentation |

Figure 6.1: Icosahedron with an inscribed true cross
• define Stallings folding
• deduce Nielsen–Schreier and Nielsen basis
• deduce algorithms for generalized word problem, conjugation, etc.
• deduce Howson’s theorem
• think about 2-cell replacement for folding; better proofs in HoTT?
• move decidability results to main flow
• include undecidability of word problem in general – doesn’t depend
  on presentation (for classes closed under inverse images of monoid
  homomorphisms)
• describe $F(S)/H$ in the case where $H$ has infinite index
• describe normal closure of $R$ in $F(S)$ – still f.g.? – get Cayley graph of
  $F(S)/(R)$. – Todd-Coxeter algorithm?
• in good cases we can recognize $S(R)$ as a “fundamental domain” in
  Cayley graph of $\langle S \mid R \rangle$.

Remark 6.1.1. In this chapter, we use letters from the beginning of the
alphabet $a, b, c, \ldots$ to denote generators, and we use the corresponding
capital letters $A, B, C$ to denote their inverses, so, e.g., $aA = Aa = 1$. This
cleans up the notational clutter significantly.

Do we fix $S$, a finite set $S = \{a, b, \ldots\}$? Mostly $F$ will denote the free
group on $S$. And for almost all examples, we take $S = \{a, b\}$.

6.2 Free groups

We have seen in Example 4.4.17 that the group of integers $\mathbb{Z}$ is the free
group on one generator in the sense that the set of homomorphisms
from $\mathbb{Z}$ to any group $G$ is equivalent (by evaluation at the loop) to the
underlying set of elements of $G$, $UG$. This set is of course equivalent (by
evaluation at the unique element) to the set of maps $(1 \to UG)$.

Likewise, we have seen in Corollary 4.16.5 that the binary sum $\mathbb{Z} \lor \mathbb{Z}$ is the free
group on two generators, corresponding to the left and right
summands.

In general, a free group on a set of generators $S$ is a group $F_S$ with
specified elements $\iota_s : UF_S$ labeled by $s : S$, such that evaluation gives an
equivalence $\text{Hom}(F_S, G) \cong (S \to UG)$ for each group $G$.

We now give a definition of the classifying type of a free group as a
higher inductive type that is very much like that of the circle, except
that instead of having a single generating loop, it has a loop $\bigcirc_s$ for each
element $s : S$.

Definition 6.2.1. Fix a set $S$. The classifying type of the free group on $S$,
$BF_S$, is a type with a point $\cdot : BF_S$ and a constructor $\bigcirc : S \to \cdot \xrightarrow{\sim} \cdot$.

Let $A(x)$ be a type for every element $x : BF_S$. The induction principle
for $BF_S$ states that, in order to define an element of $A(x)$ for every $x : BF_S$,
it suffices to give an element $a$ of $A(\cdot)$ together with an identification
$l_s : a \xrightarrow{\sim} a$ for every $s : S$. The function $f$ thus defined satisfies $f(\cdot) \equiv a$
and we are provided identifications $\text{apd}_f(\bigcirc_s) \xrightarrow{\sim} l_s$ for each $s : S$.

We define the free group on $S$ as $F_S \equiv \Omega(BF_S, \cdot)$.
A priori, $F_S$ is only an $\infty$-group. Nevertheless, we get immediately from the induction principle that evaluation at the elements of $S$ gives an equivalence $\text{Hom}(F_S, G) \rightarrowtail (S \rightarrow UG)$ for each $\infty$-group $G$.

In order to see that $F_S$ is a group, we need to know that $BF_S$ is a groupoid. This follows from a general theorem on identifications in pushouts due to Wärn. Here we restrict our discussion to decidable sets $S$, where we can give a more concrete proof.

We can follow that same strategy as in Theorem 3.4.5 and Lemma 4.16.7 and show this by giving a description of $F_S$ as an abstract group. To see what this should be, think about how symmetries of $\cdot$ we can write using the constructors $\cup_s$ for $s : S$. We can compose these out of $\cup_s$ and $\cup_{s^{-1}}$ with various generators $s$. However, if we at any point have $\cup_s \cup_{s^{-1}}$ or $\cup_{s^{-1}} \cup_s$, then these cancel. This motivates the following definitions.

**Definition 6.2.2.** Fix a decidable set $S$. Let $\tilde{S} \equiv S + S$ be the (decidable) set of signed letters from $S$. Also, let $\sim : \tilde{S} \rightarrow \tilde{S}$ be the equivalence that swaps the copies of $S$. This map is an involution called complementation.

If $a : S$, we’ll also write $a : \tilde{S}$ for the left inclusion, and we’ll write $A \equiv \tilde{a} : \tilde{S}$ for the right inclusion, so that $\tilde{a} \equiv A$ and $\tilde{A} \equiv a$, i.e., $a$ and $A$ are complementary.

**Definition 6.2.3.** For any set $T$, let $T^*$ be the set of finite lists of elements of $T$. This is the inductive type with constructors $e : T^*$ (the empty list) and concatenation of type $T \rightarrow T^* \rightarrow T^*$, taking an element $t : T$ and a list $\ell$ to the extended list $t \ell$ consisting of $t$ followed by the elements of $\ell$.

Instead of “lists” we often speak about “words” formed from “letters” taking from the set $T$, which is thus a kind of “alphabet”.

If we take $T \equiv \tilde{S}$ we get the set of words in the signed letters from $S$. If we have $a, b : S$, we find among the elements of $\tilde{S}^*$ the following:

$$\varepsilon, a, b, A, B, aA, ab, aA, aB, ba, bb, bA, bB, Aa, Ab, AA, AB, \ldots$$

When we interpret these as symmetries in $BF_S$, i.e., as elements in $UF_S$, the words $aA$ and $Bb$, etc., become trivial.

**Definition 6.2.4.** A word $w : \tilde{S}^*$ is called reduced if it doesn’t contain any consecutive pairs of complementary letters. The map $\rho_S : \tilde{S}^* \rightarrow \tilde{S}^*$ maps a word to its reduction, which is obtained by repeatedly deleting consecutive pairs of complementary letters until none remain.

**Exercise 6.2.5.** Complete the definition of $\rho_S$ by nested induction on words.\(^3\)

**Definition 6.2.6.** We define $R_S$ to be the image of $\rho_S$ in $\tilde{S}^*$, whose elements are the reduced words. We define $D_S$ to be the fiber of $\rho_S$ at the empty word, $\rho_S^{-1}(\varepsilon)$, whose elements are called Dyck words.\(^4\)

**Remark 6.2.7.** Like any map, $\rho_S$ induces an equivalence relation $\sim$ on the set $\tilde{S}^*$ where two words $u, v$ are related if and only if they map to the same reduced word, in other words, $u \sim v$ if and only if $\rho_S(u) = \rho_S(v)$. Thus, $\rho_S$ induces an equivalence $\tilde{S}^*/\sim \rightarrow R_S$.

We are now ready to prove that set $R_S$ of reduced words is equivalent to $UF_S$. We’ll do this be defining an interpretation function from words to elements of the free group.

\(^3\)Hint: This is precisely the point where we need $S$ to have decidable equality.

\(^4\)Considered as a set of words, $D_S$ is called the 2-sided Dyck language. Perhaps the 1-sided Dyck language is more familiar in language theory: Here, $S$ is considered as a set of ‘opening parentheses’, while the complementary elements are ‘closing parentheses’. For example, the 1-sided Dyck language for $\tilde{S} = \{(,\})$ consists of all balanced words of opening and closing parentheses, e.g., $(), (())$, etc., while our $D_S$ in this case also has words like $\rangle(\rangle$ and $)(\rangle\rangle$.

\(\top\)
Definition 6.2.8. We define \([\_\_]:S^*\to UF_S\) by induction on words by setting
\[
\begin{align*}
[\varepsilon] & \equiv \text{refl}, \\
[a_1 \ldots a_n w] & \equiv \bigcup_{a}\bullet [w], \quad \text{for } a:S,
\end{align*}
\]
\[
\bigwedge_{a}[aw] \equiv [aw], \quad \text{for } a:S.
\]

Theorem 6.2.9. Fix a decidable set \(S\). The interpretation map \([\_\_]\) restricts to an equivalence, denoted the same way, \([\_\_]:RS\to UF_S\).

Proof. We extend \(RS\) to an \(FS\)-set, \(RS:BF_S\to \text{Set}\), where we define \(RS(x)\) by induction on \(x:BF_S\), with
\[
RS(*) \equiv RS, \quad \text{and } RS(\bigcup_{a}) := \bigcup_{a}, \quad \text{for } a:S.
\]

Here \(s:S\to RS\) is the equivalence sending a word \(w\) to \(\rho_S(aw)\), whose inverse sends \(w\) to \(\rho_S(Aw)\). These operations are indeed mutual inverses, since \(aAw \sim Aw\).

Our goal now is to extend the definition of \([\_\_]\) to \([\_\_]:RS(x)\to P_x\), where \(P_x) \equiv (\cdot \rightarrow x), \text{ for } x:BF_S\), so that this is an inverse to the map given by transport of \(\varepsilon, \tau_x: (\cdot \rightarrow x) \to RS(x)\), with \(\tau_x(p) \equiv \text{trp}_{P_x}(\varepsilon)\).

Thinking back to Definition 3.3.4, we define \(\_\_\_\\_\_x\) by induction on \(x\) with \([\_\_\_\_\_\_] \equiv [\_\_]\), and using \([aw] \equiv \bigcup_{a}[w]\).

We get an identification \(\_\_\_\_\_\_\_\_\_ \circ \tau_x \approx \text{id}\) by path induction, since \([\varepsilon] \equiv \text{refl}\).

To prove the proposition \(\tau_x([w]) = w\) for all \(x:BF_S\) and \(w:RS(x)\), it suffices to consider the case \(x = \bullet\), since \(BF_S\) is connected. We prove that \(\tau_x([w]) \sim w\) holds for all words \(w:S^*\) by induction on \(w\), because then it follows that \(\tau_x([w]) = w\) for reduced words \(w\). The case \(w = \varepsilon\) is trivial.

In the step case for adding \(a:S\), we calculate,
\[
\tau_x([aw]) = \text{trp}_{\bigcup_{a}[w]}(\varepsilon) = \text{trp}_{\bigcup_{a}[w]}(\varepsilon([aw])) = s_a(w) = \rho_S(aw) \sim aw,
\]
as desired, the complementary case being similar.

Exercise 6.2.10. Construct an equivalence \(R_1 \sim Z\) sending \(\varepsilon\) to 0 such that \(s\), corresponds to \(s\), where \(s:\bullet\) is the unique element. This gives us two more options to add to the list in Footnote 7 on Page 63: \(\setminus\to\) and \(R_1\).

Exercise 6.2.11. Construct an equivalence \(F_n/\setminus_{\setminus\to} F_n\setminus Z\) for each \(n:N\) using the universal properties. As a result, give identifications
\[
F_n \sim ((\setminus_\setminus Z) \setminus \cdots \setminus Z),
\]
for \(n:N\), where there are \(n\) copies of \(Z\) on the right-hand side.

6.3 Graphs and Cayley graphs

We have seen in the previous chapter how cyclic groups (those generated by a single generator) have neatly described types of torsors. Indeed, \(BC_n \equiv \text{Cyc}_n\), where \(\text{Cyc}_n\) is the type of \(n\)-cycles, and the classifying type of the integers, \(BZ \equiv S^1\), i.e., the circle, is equivalent to the type of infinite cycles, \(\text{Cyc}_\infty\). In Chapter 3, we defined the types of (finite or infinite) cycles as certain components of \(\Sigma_X:(X \rightarrow X)\), but we can equivalently
consider components of $\sum_X:U(X \to X)$, since the former is a subtype of the latter. By thinking of functions in terms of their graphs, we might as well look at components of $\sum_X:U(X \to X \to U)$.

In this section we shall generalize this story to groups $G$ generated by a (finite or just decidable) set of generators $S$.

First recall from Cayley’s Theorem 4.11.7 that any group $G$ can be realized as a subgroup of the permutation group on the underlying set of elements of $G$, $UG$. In this description, a $G$-shape is a set $X$ equipped a $G$-action that defines a $G$-torsor, which in turn can be expressed as the structure of a map $a:UG \to X \to X$ satisfying certain properties.

It may happen that already $a$ restricted to a subset $S$ of $UG$ suffices to specify the action. In that case we say that $S$ generates $G$, though we’ll take the following as the official definition.

**Definition 6.3.1.** Let $G$ be a group and $S$ be a subset of $UG$, given by an inclusion $i:S \to UG$. We say that $S$ generates $G$ if the induced homomorphism from the free group on $S$, $F_S \to G$, is an epimorphism.

**Lemma 6.3.2.** Let $G$ be a group and $i:S \to UG$ an inclusion of a subset of the elements of $G$. Then $S$ generates $G$ if and only if the map

\[ \rho_S:BG \to \sum_{X:U} (S \to X \to X), \quad \rho_S(t) \equiv (t \mapsto \text{sh}_{G}, s \mapsto i(s) \cdot _{t}) \]

is an embedding.

In this case, then, $G$ can be identified with the automorphism group of $\rho_S(\text{sh}_G)$ in the type $\sum_X:U(S \to X \to X)$, or even in the larger type (of which it’s a subtype), $\sum_{X:U}(S \to X \to X \to U)$.

Also note that $S$ generates $G$ if and only if the map on elements $UF_S \to UG$ is surjective, meaning every element of $G$ can be expressed as a product of the letters in a (reduced) word from $R_S$, interpreted according to the inclusion of $S$ into $UG$. This is the case for example for $S$ consisting of the transpositions $(1\ 2), (2\ 3)$ in $\Sigma_3$, as illustrated in Fig. 6.2, where the blue color represents $(1\ 2)$ and the red color represents $(2\ 3)$.

Before we give the proof of Lemma 6.3.2, let us study these types more closely.

**Definition 6.3.3.** An $S$-labeled graph is an element $(V, E)$ of the type $\sum_{V:U}(S \to V \to V \to U)$. The first component $V$ is called the type of...
vertices of the graph, and the type \( E(s, x, y) \) is called the type of \( s \)-colored edges from \( x \) (the source) to \( y \) (the target).

If for every vertex \( x : V \) and every color \( s : S \) there is unique \( s \)-colored edge out of \( x \), i.e., the type \( \sum_{y : V} E(s, x, y) \) is contractible, then we say that the graph is functional. This means that the graph lives in the subtype \( \sum_{x : U} (S \to V \to V) \), as is the case for the graph \( \rho_3(\text{sh}_G) \) for a group \( G \).

This graph is called the Cayley graph of \( G \) with respect to the set \( S \):

**Definition 6.3.4.** The Cayley graph of a group \( G \) with respect to a generating subset \( S \) is the graph \( \text{Cay}(G; S) \) is the \( S \)-colored graph with vertices \( U_G \) and edges \( S \times U_G \) where the edge \((s, g)\) gives rise to source \( g \), target \( sg \), and color \( s \).

Convince yourself that this is really an equivalent description of \( \rho_3(\text{sh}_G) \) considered as an \( S \)-colored graph.

If \( S \) is contractible (so there’s only one color), then we just say graph, and then we simplify the type of edges to \( V \to V \to U \). Of course, every \( S \)-labeled graph \((V, E)\) gives rise to such an unlabeled label by summing over the colors, i.e., the type of edges from \( x \) to \( y \) in this graph is \( \sum_{s : S} E(s, x, y) \).

Another way to represent a graph is to sum over all the sources and targets (and colors), via Lemma 2.25.3, i.e., as a tuple \((V, E, s, t, c)\), where \( V : U \) is the type of vertices, \( E \) is the (total) type of edges, \( s, t : E \to V \) give the source and target of an edge, while \( c : E \to S \) gives the color (if we’re talking about \( S \)-colored graphs). In this description, to get the unlabeled graph we simply drop the last component.

Every graph \((V, E)\) (and thus every labeled graph) gives rise to a type by “gluing the edges to the vertices” defined as follows.

**Definition 6.3.5.** Fix an unlabeled graph \((V, E)\). The graph quotient\(^8\) \( V/E \) is the higher inductive type with constructors:

1. For every vertex \( x : V \) a point \([x] : V/E\).
2. For every edge \( e : E(x, y) \) an identification \( \sim_e : [x] \approx [y] \).

Let \( A(z) \) be a type for every element \( z : V/E \). The induction principle for \( V/E \) states that, in order to define an element of \( A(z) \) for every \( z : V/E \), it suffices to give elements \( a_x : A([x]) \) for every vertex \( x : V \) together with identifications \( q_e : a_x \approx a_y \) for every \( e : E(x, y) \). The function \( f \) thus defined satisfies \( f([x]) \equiv a_x \) for \( x : V \) and we are provided identifications \( \text{id}_z(\sim_e) \sim q_e \) for each \( e : E(x, y) \).

**Remark 6.3.6.** Note the similarity with the classifying type of a free group, cf. Definition 6.2.1. Indeed, if we form the (unlabeled!) graph \((1, S)\) on one vertex with \( S \) edges, then \( 1/S \) is essentially the same as \( 
\text{BF}_S \).

**Exercise 6.3.7.** An equivalence relation \( R : A \to A \to \text{Prop} \) on a set \( A \) can be regarded as a graph \((A, R)\). Construct an equivalence between set truncation of the graph quotient \( \|A/R\|_0 \) and the set quotient \( A/R \) from Definition 2.22.10 in this case. (So in the world of sets, the two notations agree.)

While we’re building up to the proof of Lemma 6.3.2 we need a description of a sum type over a graph quotient. By the above remark, this applies also to sum types over \( \text{BF}_S \).
CONSTRUCTION 6.3.8. Given a graph \( (V, E) \) and a family of types \( X : V / E \to \mathcal{U} \). Define \( V' \coloneqq \sum_{z : X(V)} \) and \( E'((v, x), (w, y)) \coloneqq \sum_{e : E(v, w)} x \xrightarrow{\gamma_e} y. \) Then we have an equivalence\(^9\)

\[
\text{flt} : \left( \sum_{z : V / E} X(z) \right) \simeq V' / E'.
\]

Implementation of Construction 6.3.8. We define functions \( \varphi : V' / E' \to \sum_{z : V / E} X(z) \) and \( \psi : \prod_{z : V / E} (X(z) \to V' / E') \) using the induction principles:

\[
\begin{align*}
\varphi([v, x]) &\equiv ([v], x) & \psi([v]) &\equiv (x \mapsto [(v, x)]) \\
\text{ap}_\varphi(\gamma_{(v, x)}) &\equiv (\gamma_v, \eta) & \text{ap}_\psi(\gamma_x) &\equiv h,
\end{align*}
\]

where we need to construct \( h : (x \mapsto [(v, x)]) \xrightarrow{\gamma} (y \mapsto [(w, y)]) \) for all \( e : E(v, w) \). By transporting in families of functions, it suffices to give an identification \( [(v, x)] \xrightarrow{\gamma_e} [(w, \text{trp}_X(x))] \) for all \( x : X([v]) \). We get this as the identification constructor \( \gamma_{(v, x)} \) for \( V' / E' \), where \( q : x \xrightarrow{\gamma} \text{trp}_X(x) \) is the identification over \( \gamma_x \), corresponding to the reflexivity identification at \( \text{trp}_X(x) \) via Definition 2.7.3.

\[\Box\]

Exercise 6.3.9. Complete the implementation by giving identifications \( \psi \circ \phi \xrightarrow{\gamma} \text{id} \) and \( \phi \circ \psi \xrightarrow{\gamma} \text{id} \), where \( \psi : \left( \sum_{z : V / E} X(z) \right) \to V' / E' \) is defined by \( \psi((z, x)) \equiv \psi(z)(x) \).

Later on we’ll need also need the following results about graph quotients.

Exercise 6.3.10. Suppose the edges \( E \) of a graph \( (V, E) \) are expressed as a binary sum \( E_0 \amalg E_1 \). (Here, it doesn’t matter whether \( E \) is expressed as a type family \( E : V \to V \to \mathcal{U} \), in which case we have a family of equivalences \( E(v, w) \xrightarrow{\gamma} E_0(v, w) \amalg E_1(v, w) \), or \( E \) is the total type of edges.)

Then we can obtain the graph quotient \( V / E \) by first gluing in the edges from \( E_0 \) and then gluing in the edges from \( E_1 \) to the resulting type \( V / E_0 \). Using the description of graphs with a total type of edges \( E \xrightarrow{\gamma} E_0 \amalg E_1 \), we have corresponding source and target maps expressed as compositions:

\[
E_1 \hookrightarrow E_0 \amalg E_1 \xrightarrow{\gamma} E \Rightarrow V \to V / E_0.
\]

Construct an equivalence \( V / E \xrightarrow{\gamma} V / (E_0 \amalg E_1) \xrightarrow{\gamma} (V / E_0) / E_1. \)

Exercise 6.3.11. Suppose we have any type \( X \) with an element \( x : X \). We can form a graph \( (X_1 \amalg 1, 1) \) with vertex type \( X_1 \amalg 1 \) and a single edge from \( \text{inl}_X \) to \( \text{inr}_0 \). Construct an equivalence \( X \xrightarrow{\gamma} (X_1 \amalg 1) / 1. \)

6.4 Examples

Proof of Lemma 6.3.2. TBD (perhaps put in graph quotients first) \[\Box\]

\(^9\)This is often called the flattening construction (or flattening lemma), as it “flattens” a sum over a graph quotient into a single graph quotient.

\(^10\)This equivalence can be visualized as follows, where \( X \) “grows a whisker” along the single edge.

Our discussion follows the work of Swan\(^11\).

6.5 Subgroups of free groups

We now study subgroups of free groups. We’ll eventually prove the Nielsen–Schreier theorem, which states that a finite index subgroup \( H \) of a free group \( F_S \) is itself a free group. Furthermore, when \( S \) is finite, the set of free generators of \( H \) is itself finite.

Recall from Definition 5.2.8 that a subgroup is (or can be represented by) a transitive \( G \)-set \( X: B G \to \text{Set} \) along with an element of \( X(\text{sh}_G) \).

**Definition 6.5.1.** A subgroup of a group \( G \) has **finite index** \( m \) if the underlying transitive \( G \)-set, \( X: B G \to \text{Set} \) is a family of finite sets of cardinality \( m \).

The is the case, of course, if and only if the set acted on, \( X(\text{sh}_G) \), is finite of cardinality \( m \). Notice that the definition doesn’t depend on the chosen element of \( X(\text{sh}_G) \), so applies equally to all conjugacy classes of the subgroup.

Recall also that the classifying type of the subgroup is the total type \( \Sigma_t: B G X(t) \) (which is pointed via the chosen point of \( X(\text{sh}_G) \)). We’ll use the Flattening Construction 6.3.8 to analyze this in case where \( G \) is the free group on a set \( S, F_S \), so we need to show that the quotient of the resulting graph is equivalent to \( \mathbb{1}/T \) for some set \( T \).

We do this by finding a “spanning tree” in the graph.

**Definition 6.5.2.** A graph \((V, E)\) is **connected** if \( V/E \) is a tree and it’s a **tree** if \( V/E \) is contractible.

**Definition 6.5.3.** A **subgraph** of a graph \((V, E)\) consists of a subtype \( h: U \hookrightarrow V \) of the vertices along with, for every pair of vertices \( v, w \) in \( U \), a subtype \( D(v, w) \) of the edges \( E(v, w) \).

If we represent graphs by source and target maps, then this amounts to embeddings \( h: U \hookrightarrow V \) and \( k: D \hookrightarrow E \) along with witnesses that the following squares commute:

\[
\begin{array}{ccc}
D & \xrightarrow{k} & E \\
\downarrow{s} & & \downarrow{s} \\
U & \xrightarrow{h} & V
\end{array}
\quad
\begin{array}{ccc}
D & \xrightarrow{k} & E \\
\downarrow{i} & & \downarrow{i} \\
U & \xrightarrow{h} & V
\end{array}
\]
Definition 6.5.4. A spanning tree in a graph \((V, E)\) is a subgraph \((U, D)\) such that \((U, D)\) is a tree, and the embedding of the vertices \(U \hookrightarrow V\) is an equivalence.

Equivalently, it’s given by subtypes of the edges (leaving the vertices alone) such that the underlying graph is a tree. Very often we’ll require that the edge embeddings are decidable, i.e., we can decide whether a given edge \(e : E(v, w)\) is part of the tree.

Lemma 6.5.5. Suppose we have a connected graph \((V, E)\) whose type of vertices decomposes as a binary sum \(V \rightharpoonup V_0 \bot V_1\) and we have \(v_0 : V_0\) and \(v_1 : V_1\). Then there merely exists an edge \(e\) either with source in \(V_0\) and target in \(V_1\) or the other way round.

The situation is illustrated in Fig. 6.4, where we assume there is an edge relation on the binary sum that gives a connected graph, and hence there must be a “crossing edge” \(e\), going either from \(V_0\) to \(V_1\) or the other way.

Proof. We may assume \(V \equiv V_0 \bot V_1\) by path induction. The idea is then to define a family of propositions \(P : V/E \rightarrow \text{Prop}\) that, on one hand is trivially true over \(V_0\) and on the other hand expresses our desired goal, the existence of a “crossing edge”, over \(V_1\).

We now define \(P(z), \text{for } z : V/E\), by the induction principle for the graph quotient \(V/E\). We set \(P(\text{inl}_0) \equiv \text{True}\) for \(v : V_0\) and

\[
P(\text{inr}_1) \equiv \left\| \sum_{u_0 : V_0, u_1 : V_1} (E(u_0, u_1) \bot E(u_1, u_0)) \right\|
\]

for \(v : V_1\). We must then prove that the propositions \(P([v])\) and \(P([v'])\) are equivalent whenever there’s an edge from \(v\) to \(v'\). This is the case by definition when \(v, v'\) lie in the same summand, and it’s also the case when they lie in different summands, since then we get a witness for the truth over \(V_1\).

Since \(V/E\) is connected, \(P\) must have a constant truth value, and since \(P(\text{inl}_0) \equiv \text{True}\), every \(P(z)\) is true. Hence also \(P(\text{inr}_1)\) is true, which is exactly what we wanted. □

Lemma 6.5.6. Fix a connected graph \((V, E)\) where \(V\) has decidable equality and \(E\) is a family of sets. For any subgraph \((U, D)\), where the embedding \(U \hookrightarrow V\) is decidable, and with vertices \(u \in U\) and \(v \in V \setminus U\), there merely exists\(^\dagger\) a larger subgraph with exactly one more vertex and one more edge, \((U \bot U, D \bot D)\) such that the induced map on graph quotients \(U/D \rightarrow (U \bot U)/(D \bot D)\) is an equivalence.

Proof. Since the embedding \(U \hookrightarrow V\) is decidable, we can write \(V\) as the binary sum \((U \bot (V \setminus U))\). Apply Lemma 6.5.5 to find a “crossing edge” \(e\), and form the new subgraph \((U \bot U, D \bot D)\) by adding the incident vertex not in \(U\) as well as the edge \(e\) itself. The embedding \(U \bot U \rightarrow V\) is still decidable, since \(V\) has decidable equality. Finally, we have

\[
(U \bot U)/(D \bot D) \Rightarrow ((U \bot U)/(D \bot D)) \Rightarrow U/D,
\]

using Exercises 6.3.10 and 6.3.11, as desired. □
Lemma 6.5.7. Let \((V, E)\) be a connected graph where \(V\) is an \(n\)-element set, and \(E\) is a family of decidable sets. Then the graph merely has a spanning tree with exactly \(n - 1\) edges.

Proof. We show by induction on \(k\), with \(1 \leq k \leq n\), that there merely exists a subgraph \((U, D)\) with \(k\) vertices, \(k - 1\) edges, and \(U / D\) contractible, i.e., the graph \((U, D)\) is a tree.

For \(k = 1\), we use that \(V / E\) is connected to get that \(V\) merely has a vertex \(v\). This then defines the desired subgraph on one vertex with no edges, and this is clearly a tree.

Suppose we have such a desired subgraph \((U, D)\) with \(k\) vertices and \(k - 1\) edges and \(k < n\). Since \(V\) is finite, there exists vertices \(u \in U\) and \(v \in V \setminus U\). Now apply Lemma 6.5.6 to get the next subgraph.

Finally, the subgraph \((U, D)\) with \(n\) vertices and \(n - 1\) edges gives the desired spanning tree, and any embedding of an \(n\)-element set in another \(n\)-element set is an equivalence.\(^{13}\)

Theorem 6.5.8 (Nielsen–Schreier Theorem). Suppose that \(S\) is a set with decidable equality and \(X : \text{BF}_S \to \text{Set}\) defines a (conjugacy class of a) finite index subgroup of \(F_S\). Then \(\sum_S : \text{BF}_S \times (x)\) is merely equivalent to \(\text{BF}_T\) for some set \(T\).

Moreover, if \(S\) is a finite set of cardinality \(n\) and the subgroup has index \(m\), then \(T\) can be taken to be a finite set of cardinality \(m(n - 1) + 1\).

Proof. By the Flattening Construction 6.3.8, we have an equivalence \(\text{flt} : (\sum_S : \text{BF}_S \times (x)) \simeq V / E\), with \(V \equiv X(\ast)\) and \(E(x, y) \equiv \sum_S (x \searrow \cup y)\).

By the finite index assumption, \(V\) is a finite set, say, of cardinality \(m > 0\), and since both \(S\) and \(X(\ast)\) are decidable, so is \(E\).

By Lemma 6.5.7, the graph \((V, E)\) merely contains a spanning tree with \(m - 1\) edges \(E_0\), and complementary edge set \(E_1\). Hence, using Exercise 6.3.10, we have a chain of equivalences:

\[
V / E \simeq (V / E_0) / E_1 \simeq 1 / E_1 \simeq \text{BF}_E
\]

This establishes the first claim with \(T \equiv E_1\).

If, furthermore, \(S\) has cardinality \(n\), then the graph \((V, E)\) has \(mn\) edges, as there are precisely \(n\) outgoing edges from each vertex. Since \(E_0\) has \(m - 1\) edges, that leaves \(mn - (m - 1) = mn - m + 1 = m(n - 1) + 1\) edges in \(E_1\), as desired. \(\square\)

(This also has an automata theoretic proof, see below.)

6.6 Intersecting subgroups

Stallings folding\(^{14}\).

Theorem 6.6.1. Let \(H\) be a finitely generated subgroup of \(F(S)\) and let \(u \in S^+\) be a reduced word. Then \(u\) represents an element of \(H\) if and only if \(u\) is recognized by the Stallings automaton \(S(H)\).

Theorem 6.6.2. Let \(H\) be a finitely generated subgroup of \(F(S)\). Then \(H\) has finite index if and only if \(S(H)\) is total.

Furthermore, in this case the index equals the number of vertices of \(S(H)\).

Corollary 6.6.3. If \(H\) has index \(n\) in \(F(S)\), then \(\text{rk} \, H = 1 + n(\text{card} \, S - 1)\).
Theorem 6.6.4. Suppose $H_1, H_2$ are two subgroups of $F$ with finite indices $h_1, h_2$. Then the intersection $H_1 \cap H_2$ has finite index at most $h_1 h_2$.

6.7 Connections with automata (*)

$(S$ is still a fixed finite set.)

Let $i : F(S) \to \tilde{S}^*$ map an element of the free group to the corresponding reduced word. The kernel of $i$ is the 2-sided Dyck language $D_S$.

The following theorem is due to Benois.

Theorem 6.7.1. A subset $X$ of $F(S)$ is rational if and only if $i(X) \subseteq \tilde{S}^*$ is a regular language.

Lemma 6.7.2. Let $\rho : S^* \to \tilde{S}^*$ map a word to its reduction. Then $\rho$ maps regular languages to regular languages.

The following is due to Sénizergues:

Theorem 6.7.3. A rational subset of $F(S)$ is either disjunctive or recognizable.

Given a surjective monoid homomorphism $\alpha : S^* \to G$, we define the corresponding matched homomorphism $\tilde{\alpha} : \tilde{S}^* \to G$ by $(\tilde{\alpha}(a^{-1}) \equiv \alpha(a)^{-1}$.

Theorem 6.7.4 (?). Consider a f.g. group $G$ with a surjective homomorphism $\alpha : F(S) \to G$. A subset $X$ of $G$ is recognizable by a finite $G$-action if and only if $\tilde{\alpha}^{-1}(X) \subseteq \tilde{S}^*$ is rational (i.e., regular).

Theorem 6.7.5 (Chomsky–Schützenberger). A language $L \subseteq T^*$ is context-free if and only if $L = h(R \cap D_S)$ for some finite $S$, where $h : T^* \to \tilde{S}^*$ is a homomorphism, $R \subseteq \tilde{S}^*$ is a regular language, and $D_S$ is the Dyck language for $S$.$^{15}$

Theorem 6.7.6 (Muller–Schupp, ?). Suppose $\tilde{\alpha} : \tilde{S}^* \to G$ is a surjective matched homomorphism onto a group $G$. Then $G$ is virtually free (i.e., $G$ has a normal free subgroup of finite index) if and only if $\ker(\tilde{\alpha})$ is a context-free language.

The Stallings automaton is an inverse automaton: it’s deterministic, and there’s an edge $(p, a, q)$ if and only if there’s one $(q, A, p)$. We can always think of the latter as the reverse edge. (It’s then also deterministic in the reverse direction.)

Two vertices $p, q$ get identified in the Stallings graph/automaton if and only if there is a run from $p$ to $q$ with a word $w$ whose reduction is 1. (So a word like $aAAAABBbbb$.)

Theorem 6.7.7. Let $X \subseteq F(S)$. Then $Y$ is a coset $Hw$ with $H$ a finitely generated subgroup, if and only if there is a finite state inverse automaton whose language (after reduction) is $Y$.

Corollary 6.7.9. The generalized word problem in $F(S)$ is solvable: Given a finitely generated subgroup $H$, and a word $u : \tilde{S}^*$, we can decide whether $u$ represents an element of $H$.

As above, we get a basis for $H$ as a free group from a spanning tree in $S(H)$.

Theorem 6.7.10. We can decide whether two f.g. subgroups of $F(S)$ are conjugate. Moreover, a f.g. subgroup $H$ is normal if and only if $S(H)$ is vertex-transitive.

Proof. $G, H$ are conjugate of and only if their cores are equal. $\Box$

The qualitative part of Theorem 6.6.4 is known as Howson’s theorem, while the inequality is known as Hanna Neumann’s inequality. Hanna’s son, Walter Neumann, conjectured that the 2 could be removed, and this was later proved independently by Joel Friedman and Igor Mineyev.

The Stallings automaton for $H$ can be constructed in time $O(n \log^2 n)$, where $n$ is the sum of the lengths of the generators for $H$. [Cite: Touikan: A fast algorithm for Stallings’ folding process.] Once this has been constructed, we can solve membership in $H$ in linear time.
There are other connections between group theory and language theory:

**Theorem 6.7.11 (Anisimov and Seifert).** A subgroup $H$ of $G$ is rational if and only if $H$ is finitely generated.

**Theorem 6.7.12.** A subgroup $H$ of $G$ is recognizable if and only if it has finite index.
Objects having only a finite number of symmetries can be analyzed through counting arguments. The strength of this approach is stunning.

The orbit-stabilizer theorem Section 5.9 is at the basis of this analysis: if $G$ is a group and $X : BG \to \text{Set}$ is a $G$-set, then

$$X(\text{sh}_G) \cong \bigoplus_{x \in X/G} O_x$$

and each orbit set $O_x$ is equivalent to the cokernel of the inclusion $G_x \subseteq G$ of the stabilizer subgroup of $x$. Consequently, if $X(\text{sh}_G)$ is a finite set, then its cardinality is the sum of the cardinality of these cokernels. If also the set $UG$ is finite much more can be said and simple arithmetical considerations often allow us to deduce deep statements like the size of a certain subset of $X(\text{sh}_G)$ and in particular whether or not there are any fixed points.

Example 7.0.1. A typical application could go like this. If $X(\text{sh}_G)$ is a finite set with 13 elements and for some reason we know that all the orbits have cardinalities dividing 8 – which we’ll see happens if $UG$ has 8 elements – then we must have that some orbits are singletons (for a sum of positive integers dividing 8 to add up to 13, some of them must be 1). That is, $X$ has fixed points.

The classical theory of finite groups is all about symmetries coupled with simple counting arguments. Lagrange’s Theorem 5.9.3 gives the first example: if $H$ is a subgroup of $G$, then the cardinality “$|G|$” of $UG$ is divisible by $|H|$, putting severe restrictions on the possible subgroups. For instance, if $|G|$ is a prime number, then $G$ has no nontrivial proper subgroups! (actually, $G$ is necessarily a cyclic group). To prove this result we interpret $G$ as an $H$-set.

Further examples come from considering the $G$-set $\text{Sub}_G$ of subgroups of $G$ from Section 5.2. Knowledge about the $G$-set of subgroups is of vital importance for many applications and Sylow’s theorems in Section 7.4 give the first restriction on what subgroups are possible and how they can interact. The first step is Cauchy’s Theorem 7.3.2 which says that if $|G|$ is divisible by a prime $p$, then $G$ contains a cyclic subgroup of order $p$. Sylow’s theorems goes further, analyzing subgroups that have cardinality powers of $p$, culminating in very detailed and useful information about the structure of the subgroups with cardinality the maximal possible power of $p$.

Example 7.0.2. For instance, for the permutation group $\Sigma_3$, Sylow’s theorems will deduce from the simple fact $|\Sigma_3| = 6$ that $\Sigma_3$ contains a unique subgroup $|H|$ with $|H| = 3$. Since it is unique, $H$ must be a normal subgroup.
On the other hand, for $\Sigma_4$ the information $|\Sigma_4| = 24$ only suffices to
tell us that there are either 1 or 4 subgroups $K$ with $|K| = 3$, but that all
of them are conjugate. However, the inclusion of $\Sigma_3$ in $\Sigma_4$ shows that
the $H \subseteq \Sigma_3$ above (which is given by the cyclic permutations of three
letters) can be viewed as a subgroup of $\Sigma_4$, and elementary inspection
gives that this subgroup is not normal. Hence there must be more than
one subgroup $K$ with $|K| = 3$, pinning the number of such subgroups
down to 4.

Indeed, $\Sigma_n$ has $n(n-1)(n-2)/6$ subgroups of order 3 (for $n > 2$),
but when $n > 5$ something like a phase transformation happens: the
subgroups of order 3 are no longer all conjugate. This can either be
seen as a manifestation of the fact that $3^2 = 9$ divides $n! = |\Sigma_n|$ for
$n > 5$ or more concretely by observing that there is room for “disjoint”
cyclic permutations. For instance the subgroup of cyclic permutations of
$\{1,2,3\}$ will not be conjugate to the subgroup of cyclic permutations of
$\{4,5,6\}$. Together these two cyclic subgroups give a subgroup $K$ with
$|K| = 9$ and there are 10 of these (one for each subset of $\{1,2,3,4,5,6\}$
of cardinality 3).

Remark 7.0.3. One should observe that the number of subgroups is
often very large and the structure is often quite involved, even for
groups with a fairly manageable size and transparent structure (for
instance, the number of subgroups of the group you get by taking the
product of the cyclic group $C_2$ with itself $n$ times grows approximately
as $7 \cdot 2^{n^2/4}$—e.g., $C_2 \times \cdots \times C_2^{18}$ has 17741753171749626840952685
subgroups, see https://oeis.org/A006116).

7.1 Brief overview of the chapter

We start by giving the above-mentioned counting version Lemma 7.2.3 of
Lagrange’s theorem Theorem 5.9.3. We then moves on to prove Cauchy’s
Theorem 7.3.2 stating that any finite group whose cardinality is divisible
by a prime $p$ has a cyclic subgroup of cardinality $p$. Cauchy’s theorem
has many applications, and we use it already in Section 7.4 in the proof of
Sylow’s Theorems which give detailed information about the subgroups
of a given finite group $G$. Sylow’s theorems is basically a study of the
$G$-set of subgroups of $G$ from a counting perspective. In particular, if
$p^n$ divides the cardinality of $G$, but $p^{n+1}$ does not, then Sylow’s Third
Theorem 7.4.5 gives valuable information about the cardinality of the
$G$-set of subgroups of $G$ of cardinality $p^n$.

7.2 Lagrange’s theorem, counting version

We start our investigation by giving the version of Lagrange’s theorem
which has to do with counting, but first we pin down some language.

Definition 7.2.1. A finite group is a group such that the set $UG$, is finite. If
$G$ is a finite group, then the cardinality $|G|$ is the cardinality of the finite
set $UG$ (i.e., $UG : \text{FinSet}_{|G|}$).

Example 7.2.2. The trivial group has cardinality 1, the cyclic group $C_n$ of
order $n$ has cardinality $n$ and the permutation group $\Sigma_n$ has cardinality
$n!$. 

rem:noofsubgps
In the literature, “order” and “cardinality” are used interchangeably for groups.

For finite groups, Lagrange’s Theorem 5.9.3 takes on the form of a counting argument

**Lemma 7.2.3 (Lagrange’s theorem: counting version).** Let \( i : \text{Hom}(H, G) \) be a subgroup of a finite group \( G \). Then

\[ |G| = |G/H| \cdot |H|. \]

If \( |H| = |G| \), then \( H = G \) (as subgroups of \( G \)).

**Proof.** Consider the \( H \)-action of \( G \); i.e., the \( H \)-set \( i^*G: BH \to \text{Set} \) with \( i^*G(x) \equiv (\text{sh}_G = Bi(x)) \), so that \( G/H \) is just another name for the orbits \( i^*G/H \equiv \sum_{x:BH} i^*G(x) \). Note that composing with the structure identity \( p_1: \text{sh}_G = Bi(\text{sh}_H) \) gives an equivalence \( i^*G(\text{sh}_H) \simeq UG \), so that \( |i^*G(\text{sh}_H)| = |G| \).

Lagrange’s Theorem 5.9.3 says that \( i^*G \) is a free \( H \)-set \(^1\) and so all orbits \( O_x \) are equivalent to the \( H \)-set \( H(x) = (\text{sh}_H = x) \). Consequently, the equivalence

\[ i^*G(\text{sh}_H) \simeq \sum_{x:i^*G/H} O_x \]

of Section 5.9 gives that \( G/H \) and \( H \) are finite and that \( |G| = |G/H| \cdot |H| \). \(^2\)

Finally, since we are considering a subgroup, the preimage \( Bi^{-1}(\text{pt}) \) is equivalent to the set \( G/H \). If \( |H| = |G| \), then \( |G/H| = 1 \) and so the set \( G/H \) is contractible. \( \square \)

**Corollary 7.2.4.** If \( p \) is a prime, then the cyclic group \( C_p \) has no non-trivial proper subgroups.

**Proof.** By Lagrange’s counting Lemma 7.2.3 a subgroup of \( C_p \) has cardinality dividing \( p = |C_p| \), i.e., either 1 or \( p \). \( \square \)

**Corollary 7.2.5.** Let \( f : \text{Hom}(G, G') \) be a surjective homomorphism with kernel \( N \) and let \( H \) be a subgroup of \( G \). If \( H \) and \( G' \) are finite with coprime cardinalities, then \( H \) is a subgroup of \( N \).

**Proof.** Let \( i : \text{Hom}(H, G) \) be the inclusion. By Lemma 5.6.2 the intersection \( N \cap H \) is the kernel of the composite \( f i : \text{Hom}(H, G') \). Let \( H' \) be the image of \( f i \). Now, Lagrange’s counting Lemma 7.2.3 gives that \( |H| = |H'| \cdot |N \cap H| \) and \( |G'| = |G'/H'| \cdot |H'| \). This means that \( |H'| \) divides both \( |H| \) and \( |G'| \), but since these numbers are coprime we must have that \( |H'| = 1 \), and finally that \( |H| = |N \cap H| \). This implies that \( N \cap H = H \), or in other words, that \( H \) is a subgroup of \( N \) ((elaborate)). \( \square \)

**Corollary 7.2.6.** If \( G \) and \( G' \) are finite groups, then the cardinality \( |G \times G'| \) of the product is the product \( |G| \cdot |G'| \) of the cardinalities.

**Remark 7.2.7.** Hence the cardinality of the \( n \)-fold product of Remark 7.0.3 of \( C_2 \) with itself is \( (2^n \text{ and so grows quickly, but is still}) \) dwarfed by the number of subgroups as \( n \) grows. \( \downarrow \)

\(^1\)Theorem 5.9.3 doesn’t say this at present: fix it

\(^2\)Somewhere: prove that if \( A \) is a finite set and \( B(a) \) is a family of finite sets indexed over \( a : A \), then

\[ \sum_{a:A} B(a) \]

is a finite set of cardinality \( \sum_{a:A} |B(a)| \) for any \( f : n = A \), hence if \( m = |B(a)| \) for all \( a \) then

\[ |\sum_{a:A} B(a)| = n \cdot m. \]
7.3 Cauchy's theorem

**Lemma 7.3.1.** Let \( p \) be a prime and \( G \) a group of cardinality \( p^n \) for some positive \( n : \mathbb{N} \). If \( X : BG \rightarrow \text{Set} \) is a non-empty finite \( G \)-set such that the cardinality of \( X(\text{sh}_G) \) is divisible by \( p \), then the cardinality of the set of fixed points \( X^G \equiv \prod_{Z : BG} X(z) \) is divisible by \( p \).

**Proof.** Recall that the evaluation at \( \text{sh}_G \) gives an injection of sets \( X^G \rightarrow X(\text{sh}_G) \) through which we identify \( X^G \) with the subset “\( X(\text{sh}_G)^G \)” of all trivial orbits of \( X(\text{sh}_G) \). The orbits of \( X(\text{sh}_G)^3 \) all have cardinalities that divide the cardinality \( p^n \) of \( G \). This means that all the the cardinalities of the non-trivial orbits (as well as of \( X(\text{sh}_G) \)) are positive integers divisible by \( p \).

Burnside’s Lemma Section 5.11 states that \( X(\text{sh}_G) \) is the sum of its orbits. Hence the cardinality of the set of all trivial orbits, i.e., of \( X^G \), is the difference of two numbers both divisible by \( p \). \( \square \)

**Theorem 7.3.2.** Let \( p \) be a prime and let \( G \) be a finite group of cardinality divisible by \( p \). Then \( G \) has a subgroup which is cyclic of cardinality \( p \).

**Proof.** Recall the cyclic group \( C_p \equiv \text{Aut}_{\text{cyc}} \mathbb{Z}/p \) of cardinality \( p \) where \( \mathbb{Z}/p \equiv (p, s) \) is the standard \( p \)-cycle. In other words, there is an identification of pointed groupoids

\[
\text{BC}_p \cong \left( \sum_{S : \text{Set}} \sum_{j : S \rightarrow S} ||(S, j) = \mathbb{Z}/p||, (Z/p, 1) \right).
\]

Informally, \( \text{BC}_p \) consists of pairs \((S, j)\), where \( S \) is a set of cardinality \( p \) and \( j : S \rightarrow S \) is a cyclic permutation in the sense that for \( 0 < k < p \) we have that \( j^k \) is not refl while \( j^p = \text{refl} \). Given a set \( A \), a function \( a : p \rightarrow A \) is an ordered \( p \)-tuple of elements of \( A \); it suffices to write \( a_i \) for \( a(i) \) to retrieve the usual notations for tuples. Given \((S, j) : \text{BC}_p \), however, functions \( S \rightarrow A \) cannot really be thought the same because \( S \) is not explicitly enumerated. But as soon as we are given \( q : Z/p \rightarrow (S, j) \), then functions \( S \rightarrow A \) are just as good to model ordered \( p \)-tuples of \( A \) (just by precomposing with the first projection of \( q \)). With this in mind, define \( \mu_p : (p \rightarrow UG) \rightarrow UG \) to be the \( p \)-ary multiplication, meaning \( \mu_p(g) \equiv g_0 \cdot g_1 \cdot \ldots \cdot g_{p-1} \). Then, one can define \( \mu : \prod_{(S, j) : \text{BC}_p} (Z/p \rightarrow (S, j)) \rightarrow (S \rightarrow UG) \rightarrow UG \) by \( \mu((S, j))(g) \equiv (gq)_0 \cdot \ldots \cdot (gq)_{p-1} \) (where we use \( gq \) abusively to denote the composition of \( g \) with the equivalence given by applying the first projection to the identification \( q \)). We can now define the \( C_p \)-set \((S, j) : \text{BC}_p \rightarrow \) Set as:

\[
X(S, j) \equiv \sum_{g : S \rightarrow UG} q : Z/p \rightarrow (S, j) \prod_{(S, j)(g)} = e_G.
\]

In particular, an element of \( X(Z/p) \) is a tuple \((g_0, \ldots, g_{p-1})\) satisfying that \( g_0 \cdot \ldots \cdot g_{p-1} = e_G \) for every \( \sigma : U C_p \). Note that this is equivalent to the set of tuples \((g_0, \ldots, g_{p-1})\) satisfying that \( g_0 \cdot \ldots \cdot g_{p-1} = e_G \). So, the map \( X(Z/p) \rightarrow UG^{p-1} \) that send an element \((g_0, \ldots, g_{p-1})\) to \((g_1, \ldots, g_{p-1})\) is an equivalence (the condition \( g_0 \cdot \ldots \cdot g_{p-1} = e_G \) says exactly that we can reconstruct \( g_0 \) from \((g_1, \ldots, g_{p-1})\)). In particular, \( p \) divides the cardinality of \( X(Z/p) \).

Now, a \( C_p \)-fixed points of \( X \), that is an element \( f : \prod_{(S, j) : \text{BC}_p} X(S, j) \), will have \( f_{Z/p} \) being an element \((g_0, \ldots, g_{p-1})\) of \( X(Z/p) \) that satisfies (in

\[
\text{or of } X? \text{ Reference for identification of orbits with quotients by stabilizers}
\]
In particular, \((g_0, \ldots, g_{p-1}) = (g_1, \ldots, g_{p-1}, g_0)\), i.e., such that \(g_0 = g_1 = g_2 = \cdots = g_{p-1}\). In other words, a fixed point \(f\) is such that \(f_{Z/p} : X(Z/p)\) is of the form \((g, \ldots, g)\) where \(g\) satisfies \(g^p = e_G\). So, there is a map 
\[ev : X^{C_r} \to \sum_{g : UG} g^p = e_G\]
simply given by evaluation at \(Z/p\). This map is an equivalence. Indeed, each fiber of \(ev\) is already a proposition, and we only need to show that each is inhabited. Given any \(g : UG\) such that \(g^p = e_G\), and given \((S, j) : BC_p\), one can consider the constant function \(\hat{g} : S \to UG\) given by \(\hat{g}(s) = g\) for all \(s : S\). Then, for all \(q : Z/p \cong (S, j)\), \(\hat{g}_q\) is the tuple \((g, \ldots, g)\), so that we have \((\hat{g}_q, t) : X(S, j)\). In other words, we just constructed a fixed point of \(X\) whose image through \(ev\) is \(g\), that is an element of the fiber of \(ev\) at \(g\). In particular, \(X^{C_r}\) is not empty as it is equivalent to \(\sum_{g : UG} g^p = e_G\), which contains at least \(e_G\).

Now, Lemma 7.3.1 claims that \(p\) divides the cardinality of \(X^{C_r}\), and since there are fixed points, there must be at least \(p\) fixed points. One of them is the trivial one (given by \(g \equiv e_G\) above), but the others are nontrivial.

**Lemma 7.3.3.** Let be \(G\) be a finite subgroup of cardinality \(p^n\), where \(p\) is prime and \(n\) a positive integer. Then the center \(Z(G)\) of \(G\) is nontrivial. (point to center in the symmetry chapter)

**Proof.** Recall the \(G\)-set \(\text{Ad}_G : BG \to \text{Set}\) given by \(\text{Ad}_G(z) = (z = z)\). Then the map 
\[ev_{sh_G} : \prod_{z : BG} (z = z) \to UG, \quad ev_G(f) = f(sh_G)\]
has the structure of a (n abstract) inclusion of a subgroup; namely the inclusion of the center \(Z(G)\) in \(G\). The center thus represents the fixed points of the \(G\)-set \(\text{Ad}_G\). Since \(G\) has cardinality a power of \(p\), all orbits but the fixed points have cardinality divisible by \(p\). Consequently, Burnside’s lemma states that the number of fixed points, i.e., the cardinality of \(Z(G)\), must be divisible by \(p\).

**Corollary 7.3.4.** If \(G\) is a noncyclic group of cardinality \(p^2\), then \(G\) of the form \(C_p \times C_p\).

**Proof.** The center \(Z(G)\) is by Lemma 7.3.3 of cardinality \(p\) or \(p^2\). Since \(G\) is not cyclic we have that \(g^p = e_G\) for all \(g : UG\).  

**7.4 Sylow’s Theorems**

**Theorem 7.4.1.** If \(p\) is a prime, \(n \vdash \mathbb{N}\) and \(G\) a finite group whose cardinality is divisible by \(p^n\), then \(G\) has a subgroup of cardinality \(p^n\).

**Proof.** We prove the result by induction on \(n\). If \(n = 0\) we need to have a subgroup of cardinality 1, which is witnessed by the trivial subgroup. If \(n > 0\), assume by induction that \(G\) contains a subgroup \(K\) of cardinality \(p^{n-1}\). Now, \(K\) acts on the set \(G/K\). The cardinality of \(G/K\) is divisible by \(p\) (since \(p^n\) divides the cardinality of \(G\)), and so by Lemma 7.3.1 the fixed point set \((G/K)^K\) has cardinality divisible by \(p\).

Recall the Weyl group \(W_G K\). By Lemma 5.8.3,
\[|W_G K| = |(G/K)^K|,\]
and so \( W_GK \) has cardinality divisible by \( p \).

Recall the normalizer subgroup \( N_G(K) \) of \( G \) from Definition 5.8.1 and Section 5.10 and the surjective homomorphism \( p^H_G \) from \( N_G \) to \( W_GH \), whose kernel may be identified with \( H \) so that \( |N_GH| = |W_GH| \cdot |H| \) by Lagrange’s theorem.

By Cauchy’s Theorem 7.3.2 there is a subgroup \( L \) of \( W_GK \) of cardinality \( p \). Taking the preimage of \( L \) under the projection \( p^H_G : \text{Hom}(N_G, W_GH) \), or, equivalently, the pullback

\[
BH : = BL \times_{BW_GK} BN_GK,
\]

we obtain a subgroup \( H \) of \( N_G(K) \) of cardinality \( p^n \) (\( H \) is a free \( K \)-set with \( p \) orbits). The theorem is proven by considering \( H \) as a subgroup of \( G \).

\[\square\]

**Definition 7.4.2.** Let \( p^n \) be the largest power of \( p \) which divides the cardinality of \( G \). A subgroup of \( G \) of cardinality \( p^n \) is called a \( p \)-Sylow subgroup of \( G \) and \( \text{Syl}_G^p \) is the \( G \)-subset of \( \text{Sub}_G \) of \( p \)-Sylow subgroups of \( G \).

**Lemma 7.4.3.** Let \( G \) be a finite group and \( P \) a \( p \)-Sylow subgroup. Then the number of conjugates of \( P \) is not divisible by \( p \).

**Proof.** Let \( X \) be the \( G \)-set of conjugates of \( P \). Being a \( G \)-orbit, \( X \) is equivalent \( G/\text{Stab}_P \), where \( P \) is the stabilizer subgroup of \( P \). Now, \( P \) is contained in the stabilizer so the highest power of \( p \) dividing the cardinality of \( G \) also divides the cardinality of \( \text{Stab}_P \).

\[\square\]

**Theorem 7.4.4.** Let \( G \) be a finite group. Then any two \( p \)-Sylow subgroups are conjugate, or in other words, the \( G \)-set \( \text{Syl}_G^p \) is transitive.

Furthermore, if \( H \) a subgroup of \( G \) of cardinality \( p^k \) and \( P \) a \( p \)-Sylow subgroup of \( G \). Then \( H \) is conjugate to a subgroup of \( P \).

**Proof.** We prove the last claim first. Consider the set \( O_P \) of conjugates of \( P \) as an \( H \)-set. Since the cardinality of \( O_P = G/\text{Stab}_P \) is prime to \( p \) there must be an \( H \)-fixed point \( Q \). In other words, \( H \subseteq \text{Stab}_Q \). By Lemma 5.6.4 there is a conjugate \( H' \) of \( H \) with \( H' \subseteq \text{Stab}_P \). Now, \( P \subseteq \text{Stab}_P \) (ref) is a normal subgroup and so by. 7

The first claim now follows, since if both \( H \) and \( P \) are \( p \)-Sylow subgroup, then a conjugate of \( H \) is a subgroup of \( P \), but since these have the same cardinalities they must be equal.

\[\square\]

**Theorem 7.4.5.** Let \( G \) be a finite group and let \( P \) be a \( p \)-Sylow subgroup of \( G \). Then the cardinality of \( \text{Syl}_G^p \)

1. divides \( |G|/|P| \) and
2. is 1 modulo \( p \).

**Proof.** Theorem 7.4.4 claims that \( \text{Syl}_G^p \) is transitive, so as a \( G \)-set it is equivalent to \( G/\text{Stab}_P \) (\( N_GP \) is the stabilizer of \( P \) in \( \text{Sub}_G \)). Since \( P \) is a subgroup of \( N_GP \) we get that \( |P| \) divides \( N_GP \) and so \( |\text{Syl}_G^p| = |G|/|N_GP| \) divides \( |G|/|P| \).

Let \( i \) be the inclusion of \( P \) in \( G \) and consider the \( P \)-set \( i\text{Syl}_G^p \) obtained by restricting to \( P \). Since the cardinality only depends on the underlying
set we have that $|i^*\text{Syl}_p^G| = |\text{Syl}_p^G|$ and we analyze the decomposition into $P$-orbits to arrive at our conclusion.

Let $Q : i^*\text{Syl}_p^G$ be a fixed point, i.e., $P \subseteq N_G Q$. Now, since $N_G Q$ is a subgroup of $G$, we get that $|N_G Q|$ divides $|G|$, so this proves that $P$ is a $p$-Sylow subgroup of $N_G Q$. However, the facts that $Q$ is normal in $N_G Q$ and that all Sylow subgroups being conjugates together conspire to show that $P = Q$. That is, the number of fixed points in $i^*\text{Syl}_p^G$ is one. Since $P$ is a $p$-group, all the other orbits have cardinalities divisible by $p$, and so

$$|\text{Syl}_p^G| = |i^*\text{Syl}_p^G| \equiv 1 \mod p.$$

\(\square\)

((Should we include standard examples, or is this not really wanted in this book?))

Fields and vector spaces

Quotients; subspaces (= ?). Bases and so. Dual space; orthogonality. (all of this depends on good implementations of subobjects). Eigen-stuff. Characteristic polynomials; Hamilton-Cayley.

8.1 the algebraic hierarchy: groups, abelian groups, rings, fields

Definition 8.1.1. A ring \( R \) is an abstract abelian group with a binary function \((-) \cdot (-): R \times R \to R\) and an element \( 1 : R \) such that for all elements \( a : R, a \cdot 1 = a \) and \( 1 \cdot a = a \), for all elements \( a : R, b : R, c : R \), \( a \cdot (b \cdot c) = (a \cdot b) \cdot c \), for all elements \( a : R, b : R, c : R \), \( a \cdot (b + c) = a \cdot b + a \cdot c \), and for all elements \( a : R, b : R, c : R \), \( (a + b) \cdot c = a \cdot c + b \cdot c \).

Definition 8.1.2. A ring \( R \) is commutative if for all elements \( a : R, b : R \), \( a \cdot b = b \cdot a \).

Definition 8.1.3. A commutative ring \( R \) is nontrivial if \( 0 \neq 1 \)

\[ \text{isNonTrivialCRing}(R) := \text{isCRing}(R) \times (0 \neq 1) \]

Definition 8.1.4. Given a commutative ring \( R \), an element \( e : R \) is invertible if there exists an element \( a : R \) such that \( e \cdot a = 1 \) and \( a \cdot e = 1 \):

\[ \text{isInvertible}(e) := \bigg\| \sum_{a : R} (e \cdot a = 1) \times (a \cdot e = 1) \bigg\| \]

Theorem 8.1.5. In any nontrivial commutative ring \( R \), 0 is always a non-invertible element.

\[ \text{isNonTrivialCRing}(R) \to \neg \text{isInvertible}(0) \]

Proof. Suppose that 0 is invertible. Then there exists an element \( a : R \) such that \( a \cdot 0 = 1 \). However, due to the absorption properties of 0 and the fact that \( R \) is a set, \( a \cdot 0 = 0 \). This implies that \( 0 = 1 \), which contradicts the fact that \( 0 \neq 1 \) in a nontrivial commutative ring. Thus, 0 is a non-invertible element in any nontrivial commutative ring \( R \).

Definition 8.1.6. A nontrivial commutative ring \( R \) is a field if and only if the type of all non-invertible elements in \( R \) is contractible:

\[ \text{isField}(R) := \text{isNonTrivialCRing}(R) \times \text{isContr} \left( \sum_{x : R} \neg \text{isInvertible}(x) \right) \]
Equivalently, $R$ is a field if and only if every non-invertible element is equal to zero.

**Remark 8.1.7.** In other parts of the constructive mathematics literature, such as in Peter Johnstone’s *Rings, Fields, and Spectra*, this is called a "residue field". However, in this book we shall refrain from using the term "residue field" for our definition, since that contradicts the usage of "residue field" in other parts of mathematics, such as in algebraic geometry.

**Definition 8.1.8.** A field is **discrete** if every element is either invertible or equal to zero.

\[
isDiscreteField(R) := isField(R) \times \prod_{a : R} ||(a = 0) \land isInvertible(a)||
\]

**Definition 8.1.9.** A nontrivial commutative ring $R$ is a **local ring** if for every element $a : R$ and $b : R$, if the sum $a + b$ is invertible, then either $a$ is invertible or $b$ is invertible.

\[
isLocalRing(R) := isNonTrivialCRing(R) \times \prod_{a : R : R} isInvertible(a+b) \to ||isInvertible(a) \land isInvertible(b)||
\]

**Definition 8.1.10.** A field $R$ is **Heyting** if it is also a local ring.

\[
isHeytingField(R) := isField(R) \times isLocalRing(R)
\]

### 8.2 vector spaces

**Definition 8.2.1.** Given a field $K$, a $K$-**vector space** is an abelian group $V$ with a bilinear function $(-)(-): K \times V \to V$ called **scalar multiplication** such that $1v = v$ and for all elements $a : K$, $b : K$, and $v : V$, $(a \cdot b)v = a(bv)$.

**Definition 8.2.2.** A $K$-**linear map** between two $K$-vector spaces $V$ and $W$ is a group homomorphism $h : V \to W$ which also preserves scalar multiplication: for all elements $a : K$ and $v : V$, \( f(av) = af(v) \).

**Definition 8.2.3.** Given a field $K$ and a set $S$, the **free $K$-vector space** on $S$ is the homotopy initial $K$-vector space $V$ with a function $i : S \to V$: for every other $K$-vector space $W$ with a function $j : S \to W$, the type of linear maps $h : V \to W$ such that for all elements $s : S$, $h(i(s)) = j(s)$ is contractible.

**Definition 8.2.4.** Given a field $K$ and a natural number $n$, an $n$-**dimensional $K$-vector space** is a free $K$-vector space on the finite type $\text{Fin}(n)$.

In this chapter we study Euclidean geometry. We assume some standard linear algebra over real numbers, including the notion of finite dimensional vector space over the real numbers and the notion of inner product. In our context, the field of real numbers, \( \mathbb{R} \), is a set, and so are vector spaces over it. Moreover, a vector space \( V \) has an underlying additive abstract group, and we will feel free to pass from it to the corresponding group.

9.1 Inner product spaces

Definition 9.1.1. An inner product space \( V \) is a real vector space of finite dimension equipped with an inner product \( H : V \times V \to \mathbb{R} \).

Let \( \tilde{V} \) denote the type of inner product spaces. It is a type of pairs whose elements are of the form \( (V, H) \). For \( n : \mathbb{N} \), let \( \tilde{V}_n \) denote the type of inner product spaces of dimension \( n \).

For each natural number \( n \), we may construct the standard inner product space \( \mathbb{V}^n \) of dimension \( n \) as follows. For \( V \) we take the vector space \( \mathbb{R}^n \), and we equip it with the standard inner product given by the dot product

\[
H(x, y) \equiv x \cdot y,
\]

where the dot product is defined as usual as

\[
x \cdot y \equiv \sum_i x_i y_i.
\]

Theorem 9.1.2. Any inner product space \( V \) is merely equal to \( \mathbb{V}^n \), where \( n \) is \( \dim V \).

For the definition of the adverb “merely”, refer to Definition 2.16.13.

Proof. Since any finite dimensional vector space merely has a basis, we may assume we have a basis for \( V \). Now use Gram-Schmidt orthonormalization to show that \( V = \mathbb{V}^n \).

Lemma 9.1.3. The type \( \tilde{V} \) is a 1-type.

Proof. Given two inner product spaces \( V \) and \( V' \), we must show that the type \( V = V' \) is a set. By univalence, its elements correspond to the linear isomorphisms \( f : V \to V' \) that are compatible with the inner products. Those form a set.
Definition 9.1.4. Given a natural number $n$, we define the orthogonal group $O(n)$ as follows.

$$O(n) \equiv O\tilde{\mathbb{V}}_n$$

Here $\tilde{\mathbb{V}}_n$ is equipped with the basepoint provided by $\text{sh}_{O(n)} \equiv \mathbb{V}^n$, and with the proof that it is a connected groupoid provided by Theorem 9.1.2 and Lemma 9.1.3.

The standard action (in the sense of Definition 4.7.17) of $O(n)$ is an action of it on its designated shape $\mathbb{V}^n$. Letting $\text{Vect}_\mathbb{R}$ denote the type of finite dimensional real vector spaces, we may compose the standard action with the projection map $BO(n) \to \text{Vect}_\mathbb{R}$ that forgets the inner product to get an action of $O(n)$ on the vector space $\mathbb{R}^n$.

## 9.2 Euclidean spaces

In high school geometry courses, one encounters the Euclidean plane (of dimension 2) and the Euclidean space of dimension 3. The vectors and the points of Euclidean geometry are the basic ingredients, from which the other concepts are derived. Those concepts include such things as lines, line segments, triangles, tetrahedra, spheres, and so on. Symmetries of those objects are also studied: for example, an isosceles non-equilateral triangle has a total of 2 symmetries: the identity and the reflection through the midline.

So, a Euclidean space will come with two sets: a set of points and a set of vectors. The structure on the two sets includes the following items.

1. If $v$ and $w$ are vectors, then there is a vector $v + w$ called its sum.
2. If $v$ is a vector and $r$ is a real number, then there is a vector $rv$ called the scalar multiple of $v$ by $r$.
3. If $v$ is a vector, then there is a real nonnegative number called its length.
4. If $P$ and $Q$ are points, then there is a unique vector $v$ which can be “positioned” so its tail is “at” $P$ and its head is “at” $Q$. It is called the vector from $P$ to $Q$. The distance from $P$ to $Q$ is the length of $v$.
5. If $P$ is a point and $v$ is a vector, then there is a unique point $Q$ so that $v$ which can be positioned so its tail is at $P$ and its head is at $Q$. It is called the point obtained from $P$ by translation along $v$.

We introduce the (new) notation $v + P$ for the point $Q$ obtained from $P$ by translation along $v$. Another fact from high school geometry is that if $w$ is a vector, too, then the associative rule $v + (w + P) = (v + w) + P$ holds. This suggests that the essential features of high school geometry can be captured by describing the set of points as a torsor for the group of vectors.

We use that idea now to give a precise definition of Euclidean space of dimension $n$, together with its points and vectors. More complicated geometric objects will be introduced in subsequent sections.

Definition 9.2.1. A Euclidean space $E$ is an torsor $A$ for the additive group underlying an inner product space $V$. (For the definition of torsor, see Definition 4.9.1.)
We will write $V$ also for the additive group underlying $V$. Thus an expression such as $BV$ or $\text{Torsor}_V$ will be understood as applying to the underlying additive group$^1$ of $V$.

**Definition 9.2.2.** We denote the type of all Euclidean spaces of dimension $n$ by $\mathbb{E}_n = \sum_{V: \text{Vec}_n} \text{Torsor}_V$. The elements of $\text{Pts} E$ will be the points in the geometry of $E$, and the elements of $\text{Vec} E$ will be the vectors in the geometry of $E$. We let $\mathbb{E}$ denote the type of all Euclidean spaces; it is equivalent to the sum $\sum_{n: \mathbb{N}} \mathbb{E}_n$.

The torsor $\text{Pts} E$ is a nonempty set upon which $V$ acts. Since $V$ is an additive group, we prefer to write the action additively, too: given $v: V$ and $P: \text{Pts} E$ the action provides an element $v + P: \text{Pts} E$. Moreover, given $P, Q: \text{Pts} E$, there is a unique $v: V$ such $v + P = Q$; for it we introduce the notation $Q - P \equiv v$, in terms of which we have the identity $(Q - P) + P = Q$.

For each natural number $n$, we may construct the standard Euclidean space $\mathbb{E}^n : \mathbb{E}_n$ of dimension $n$ as follows. For $\text{Vec} E$ we take the standard inner product space $\mathbb{V}^n$, and for $\text{Pts} E$ we take the corresponding principal torsor $\text{Pr}_n$.

**Theorem 9.2.3.** Any Euclidean space $E$ is merely equal to $\mathbb{E}^n$, where $n$ is $\dim E$.

**Proof.** Since we are proving a proposition and any torsor is merely trivial, by Theorem 9.1.2 we may assume $\text{Vec} E$ is $\mathbb{V}^n$. Similarly, we may assume that $\text{Pts} E$ is the trivial torsor. $\square$

**Lemma 9.2.4.** The type $\mathbb{E}_n$ is a 1-type.

**Proof.** Observe using Theorem 4.8.6 that $\mathbb{E}_n = \sum_{V: \text{BO}(n)} BV$. The types $\text{BO}(n)$ and $BV$ are 1-types, so the result follows from Item (4). $\square$

**Definition 9.2.5.** Given a natural number $n$, we define the Euclidean group by

$$E(n) \equiv \Omega \mathbb{E}_n.$$ 

Here we take the basepoint of $\mathbb{E}_n$ to be $\mathbb{E}^n$, and we equip $\mathbb{E}_n$ with the proof that it is a connected groupoid provided by Theorem 9.2.3 and Lemma 9.2.4. $\square$

The standard action of $E(n)$ (in the sense of Definition 4.7.17) is an action of it on the Euclidean space $\mathbb{E}^n$.

**Theorem 9.2.6.** For each $n$, the Euclidean group $E(n)$ is equivalent to a semidirect product $O(n) \ltimes \mathbb{R}^n$.

**Proof.** Recall Definition 4.14.5 and apply it to the standard action $H: \text{BO}(n) \rightarrow \text{Group of } O(n)$ on the additive group underlying $\mathbb{R}^n$, as defined in Definition 9.1.4. The semidirect product $O(n) \ltimes \mathbb{R}^n$ has $\sum_{V: \text{BO}(n)} BV$ as its underlying pointed type. Finally, observe that $E(n) \simeq \sum_{V: \text{BO}(n)} BV$, again using Theorem 4.8.6. $\square$

### 9.3 Geometric objects

In this section, we discuss the notion of “object” in Euclidean space, but much of what we say is more general and applies equally well to other sorts of geometry, such as projective geometry or hyperbolic geometry.
Let $E$ be a Euclidean space, as defined in Definition 9.2.1. The points of $E$ are the elements of $\text{Pts } E$, and intuitively, a geometric object in $E$ ought to come with a way to tell which points of $E$ are inside the object.

For example, in the standard Euclidean plane with coordinates labelled $x$ and $y$, the $x$-axis is described by the equation $y = 0$. In other words, we have a function of type $g : \text{Pts } E \to \text{Prop}$ defined by $(x, y) \mapsto y = 0$. It’s the predicate that defines the line as a subset of the plane. More complicated objects can also be specified as sets of points of $E$ by other functions $\text{Pts } E \to \text{Prop}$. Now consider a typical Euclidean symmetry of the line, for example, the symmetry given by the function $t : (x, y) \mapsto (x + 3, y)$. It is compatible with the action of $\text{Vec } E$ on $\text{Pts } E$, and it sends the line to itself. If we consider the pair $(E, g)$ as an element of the type $\sum_{E : \mathcal{E}} (\text{Pts } E \to \text{Prop})$, then, by univalence, we see that the translation $t$ gives rise to an identification of type $(E, g) = (E, g)$.

Now suppose the object to be described is a car, as an object in a 3-dimensional Euclidean space. Then presumably we would like to give more information than just whether a point is inside the car: we may wish to distinguish points of the car by the type of material found there. For example, to distinguish the windshield (made of glass) from the hood (made of steel). Thus, letting $M$ denote the set of materials found in the car, with one extra element for the points not in the car, we may choose to model the car as a function of type $\text{Pts } E \to M$.

In order to unify the two examples above into a general framework, one may observe that Prop is a set (with 2 distinguished elements, True and False). That motivates the following definition.

**Definition 9.3.1.** Let $M$ be a set. A geometric object is a pair $(E, g)$ of type $\text{EucObj} \equiv \sum_{E : \mathcal{E}} (\text{Pts } E \to M)$. If one wishes to emphasize the role played by the set $M$, we may refer to $(E, g)$ as a geometric object with materials drawn from the set $M$.

We may also say that $(E, g)$ is a geometric object in $E$. When $M = \text{Prop}$, we will think of the object as the subset of $\text{Pts } E$ consisting of those points $P$ such that $g(P)$ holds.

**Exercise 9.3.2.** Show that $\text{EucObj}$ is a groupoid.

The exercise above allows us to speak of the symmetry group of a geometric object.

**Exercise 9.3.3.** Show that the symmetry group of a geometric object in $\mathbb{E}^n$ is a subgroup of $\text{E}(n)$.

**Exercise 9.3.4.** Let $E$ be a Euclidean space of dimension $n$, and let $P$ be a point of $E$. The subset of $\text{Pts } E$ containing just the point $P$ is defined by the predicate $Q \mapsto (Q = P)$. Show that its symmetry group is isomorphic to $\text{O}(n)$.

One often considers situations in geometry with multiple objects in the same space. For example, one may wish to consider two lines in the plane, or a point and a plane in space. This prompts the following definitions.

**Definition 9.3.5.** Suppose we are given an parameter type $I$ and a set $M_i$ for each $i \in I$. A configuration of geometric objects relative to that data is a Euclidean space $E$ together with a function $p_i : \text{Pts } E \to M_i$ for each $i \in I$. Its constituents are the geometric objects of the form $(E, p_i)$, for each $i \in I$. If $n$ is a natural number, and we let $I$ be the finite type with $n$
elements, then we may refer to the configuration as a configuration of \( n \)
objects.

**Definition 9.3.6.** Given an type \( I \) and a family of geometric objects \( T_i \)
parametrized by the elements of \( I \), an arrangement of the objects is a configuration,
also parametrized by the elements of \( I \), whose \( i \)-th consituent is merely equal to \( T_i \).

For example, suppose we consider arrangements consisting of a point and a line in
the plane. The arrangements where the point is at a distance \( d \) from the line, where \( d \geq 0 \),
are all merely equal to each other, because there is a Euclidean motion that relates any two of them. Hence, in some sense, the arrangements are classified by the set of nonnegative real numbers \( d \). This motivates the following definition.

**Definition 9.3.7.** Given an parameter type \( I \) and a collection of geometric objects \( T_i \)
parametrized by the elements of \( I \), then an incidence type between them is a connected
component of the type of all arrangements of the objects.

### 9.4 The icosahedron

**Definition 9.4.1.** The icosahedron (with side length 2) is the regular solid
in standard euclidean three-space \( \mathbb{E}^3 \) with vertices at cyclic permutations of \((0, \pm 1, \pm \varphi)\), where \( \varphi = (1 + \sqrt{5})/2 \) is the golden ratio.

**Remark 9.4.2.** The four vertices \((0, \pm 1, \pm \varphi)\) make up a golden rectangle
with short side length equal to 2. To check that the above vertices really form a regular polyhedron, we just need to calculate the length between to adjacent corners of golden rectangles:

\[
\|(0, 1, \varphi) - (1, \varphi, 0)\| = \sqrt{1 + (\varphi - 1)^2 + \varphi^2} = \sqrt{4} = 2
\]

9.9.4 projective properties (cross-ratio)
9.9.5 fundamental theorem of projective geometry
The goal of Galois theory is to study how the roots of a given polynomial can be distinguished from one another. Take for example $X^2 + 1$ as a polynomial with real coefficients. It has two distinct roots in $\mathbb{C}$, namely $i$ and $-i$. However, an observer, who is limited to the realm of $\mathbb{R}$, can not distinguish between the two. Morally speaking, from the point of view of this observer, the two roots $i$ and $-i$ are pretty much the same. Formally speaking, for any polynomial $Q: \mathbb{R}[X, Y]$, the equation $Q(i, -i) = 0$ is satisfied if and only if $Q(-i, i) = 0$ also. This property is easily understood by noticing that there is an automorphism of fields $\sigma: \mathbb{C} \rightarrow \mathbb{C}$ such that $\sigma(i) = -i$ and $\sigma(-i) = i$ which also fixes $\mathbb{R}$. The goal of this chapter is to provide the rigorous framework in which this statement holds. TODO: complete/rewrite the introduction

10.1 Covering spaces and field extensions

Recall that a field extension is simply a morphism of fields $i: k \rightarrow K$ from a field $k$ to a field $K$. Given a fixed field $k$, the type of fields extensions of $k$ is defined as

$$k\backslash\text{Fields} := \sum_{K: \text{Fields}} \text{hom}_{\text{Fields}}(k, K)$$

**Definition 10.1.1.** The Galois group of an extension $(K, i)$ of a field $K$, denoted $\text{Gal}(K, i)$ or $\text{Gal}(K/k)$ when $i$ is clear from context, is the group $\text{Aut}_{k\backslash\text{Fields}}(K, i)$.

**Remark 10.1.2.** The Structure Identity Principle holds for fields, which means that for $K, L: \text{Fields}$, one has

$$(K = L) \cong \text{Iso}(K, L)$$

where $\text{Iso}(K, L)$ denotes the type of these equivalences that are homomorphisms of fields. Indeed, if one uses $K$ and $L$ also for the carrier types of the fields, one gets:

$$K = L \cong \sum_{p: K \equiv L} (\text{trp}_p(\text{+}_K) = \text{+}_L) \times (\text{trp}_p(\cdot_K) = \cdot_L) \times (\text{trp}_p(0_K) = 0_L) \times (\text{trp}_p(1_K) = 1_L)$$

Any $p: K \equiv L$ is the image under univalence of an equivalence $\phi: K \cong L$. 

206
and then:

\[\text{trp}_p(+_K) = (x, y) \mapsto \phi(\phi^{-1}(x) +_K \phi^{-1}(y))\]
\[\text{trp}_p(\cdot_K) = (x, y) \mapsto \phi(\phi^{-1}(x) \cdot_K \phi^{-1}(y))\]
\[\text{trp}_p(0_K) = \phi(0_K)\]
\[\text{trp}_p(1_K) = \phi(1_K)\]

It follows that:

\[(K = L) \simeq \sum_{\phi : K = L} (\phi(x +_K y) = \phi(x) +_L \phi(y))\]
\[\times (\phi(x \cdot_K y) = \phi(x) \cdot_L \phi(y))\]
\[\times (\phi(0_K) = 0_L) \times (\phi(1_K) = 1_L)\]

The type on the right hand side is the same as \(\text{Iso}(K, L)\) by definition.

In particular, given an extension \((K, i)\) of \(K\):

\[\text{UGal}(K, i) \simeq \sum_{p : K = K} \text{trp}_p i = i \simeq \sum_{\sigma : \text{Iso}(K, K)} \sigma \circ i = i\]

This is how the Galois group of the extension \((K, i)\) is defined in ordinary mathematics.

Given an extension \((K, i)\) of field \(k\), there is a map of interest:

\[i^* : K \backslash \text{Fields} \to k\backslash \text{Fields}, \quad (L, j) \mapsto (L, j i)\]

**Lemma 10.1.3.** The map \(i^*\) is a set-bundle.

**Proof.** Given a field extension \((K', i')\) in \(k\backslash \text{Fields},\) one wants to prove that the fiber over \((K', i')\) is a set. Suppose \((L, j)\) and \((L', j')\) are extensions of \(K\), together with paths \(p : (K', i') = (L, ji)\) and \(p' : (K', i') = (L', j'i)\).

Recall that \(p\) and \(p'\) are respectively given by equivalences \(\pi : K' = L\) and \(\pi' : K' = L'\) such that \(\pi i' = ji\) and \(\pi' i' = j'i\). A path from \(((L, j), p)\) to \(((L', j'), p')\) in the fiber over \((K', i')\) is given a path \(q : (L, j) = (L', j')\) in \(K\backslash \text{Fields}\) such that \(\text{trp}_q p = p'\). However, such a path \(q\) is the data of an equivalence \(\phi : L = L'\) such that \(\phi j = j'\), and then the condition \(\text{trp}_q p = p'\) translates as \(\phi \pi = \pi'\). So it shows that \(\phi\) is necessarily equal to \(\pi' \pi^{-1}\), hence is unique. \(\square\)

The fiber of this map at a given extension \((L, j)\) of \(k\) is:

\[(i^*)^{-1}(L, j) \simeq \sum_{L' : \text{Fields}} \sum_{p : K = L'} (L, j) = (L', j'i)\]
\[\simeq \sum_{L' : \text{Fields}} \sum_{p : K = L'} \sum_{p j = j'i} \]
\[\simeq \sum_{j' : K = L} j = j'i\]
\[\simeq \text{hom}_k(K, L)\]

where the last type denotes the type of homomorphisms of \(k\)-algebra (the structure of \(K\) and \(L\) being given by \(i\) and \(j\) respectively).

In particular, the map \(t : \text{UGal}(K, i) \to (i^*)^{-1}(K, i)\) mapping \(g\) to \(\text{trp}_g (\text{id}_K)\) identifies with the inclusion of the \(k\)-automorphisms of \(K\) into the \(k\)-endomorphisms of \(K\).

TODO: write a section on polynomials in chapter 12.
Definition 10.1.4. Given an extension \( i : k \to K \), an element \( \alpha : K \) is algebraic if \( \alpha \) is merely a root of a polynomial with coefficients in \( k \). That is if the following proposition holds:
\[
\| \sum_{n \geq 0} a(n) \alpha^n \| = 0
\]

Definition 10.1.5. A field extension \((K, i)\) is said to be algebraic when each \( \alpha : K \) is algebraic.

Remark 10.1.6. Note that when the extension \((K, i)\) is algebraic, then \( t \) is an equivalence. However, the converse is false, as shown by the non-algebraic extension \( \mathbb{Q} \to \mathbb{R} \). We will prove that every \( \mathbb{Q} \)-endomorphism of \( \mathbb{R} \) is the identity function. Indeed, any \( \mathbb{Q} \)-endomorphism \( \varphi : \mathbb{R} \to \mathbb{R} \) is linear and sends squares to squares, hence is non-decreasing. Let us now take an irrational number \( a : \mathbb{R} \). For any rational \( p, q : \mathbb{Q} \) such that \( p < a < q \), then \( p = \varphi(p) < \varphi(a) < \varphi(q) = q \). Hence \( \varphi(a) \) is in any rational interval that \( a \) is. One deduces \( \varphi(a) = a \).

Definition 10.1.7. A field extension \( i : k \to K \) is said finite when \( K \) as a \( k \)-vector space, the structure of which is given by \( i \), is of finite dimension. In that case, the dimension is called the degree of \( i \), denoted \([K : i] \) or \([K : k]\) when \( i \) is clear from context.

10.2 Intermediate extensions and subgroups

Given two extensions \( i : k \to K \) and \( j : K \to L \), the map \( i' \) can be seen as a pointed map
\[
i' : \text{BGal}(L, j) \to \text{BGal}(L, ji), \quad x \mapsto x \circ i.
\]

Then, through Lemma 10.1.3, \( i' \) presents \( \text{Gal}(L, j) \) as a subgroup of \( \text{Gal}(L, ji) \). One goal of Galois theory is to characterize those extensions \( i' : k \to L \) for which all subgroups of \( \text{Gal}(L, i') \) arise in this way.

Given any extension \( i : k \to L \), there is an obvious \( \text{Gal}(L, i) \)-set \( X \) given by
\[
(L', i') \mapsto L'.
\]

For a pointed connected set-bundle \( g : B \to \text{BGal}(L, i) \), one can consider the type of fixed points of the \( \mathcal{Q}B \)-set \( Xf \):
\[
K \equiv (Xg)^{\mathcal{Q}B} \equiv \prod_{x \in B} X(g(x))
\]

It is a set, which can be equipped with a field structure, defined pointwise. Moreover, if one denotes \( b \) for the distinguished point of \( B \), and \( (L'', j'') \) for \( g(b) \), then, because \( g \) is pointed, one has a path \( p : L = L'' \) such that \( pi' = j'' \). There are fields extensions \( i' : k \to K \) and \( j' : K \to L \) given by:
\[
i'(a) \equiv x \mapsto \text{snd}(g(x))(a), \quad j'(f) \equiv p^{-1}f(b)
\]

In particular, for all \( a : k \), \( j'i'(a) = p^{-1} \text{snd}(g(b))(a) = p^{-1}j''(a) = i'(a) \).

Galois theory is interested in the settings when these two contructions are inverse from each other.

Historical remarks

Here we briefly sketch some of the history of groups. See the book by Wussing\(^1\) for a detailed account, as well as the shorter survey by Kleiner\(^2\). There’s also the book by Yaglom\(^3\).

Some waypoints we might mention include:

• Early nineteenth century geometry, the rise of projective geometry, Möbius and Plücker

• Early group theory in number theory, forms, power residues, Euler and Gauss.

• Permutation groups, Lagrange and Cauchy, leading (via Ruffini) to Abel and Galois.

• Liouville and Jordan\(^4\) ruminating on Galois.

• Cayley, Klein and the Erlangen Program\(^5\).

• Lie and differentiation.

• von Dyck and Hölder.

• J.H.C. Whitehead and crossed modules.

• Artin and Schreier theory.

• Algebraic groups (Borel and Chevalley et al.)

• Feit-Thompson and the classification of finite simple groups.

• Grothendieck and the homotopy hypothesis.

• Voevodsky and univalence.

---

Metamathematics is the study of mathematical theories as mathematical objects in themselves. This book is primarily a mathematical theory of symmetries. Occasionally, however, we have made statements like “the law of the excluded middle is not provable in our theory”. This is a statement about, and not in, the type theory of this book. As such it is a metamathematical statement.

Sometimes it is possible to encode statements about a theory in the language of the theory itself. Even if true, the encoded metamathematical statement can be unprovable in the theory itself. The most famous example is Gödel's second incompleteness theorem. Gödel encoded, for any theory T extending Peano Arithmetic and satisfying some general assumptions, the statement that T is consistent as a statement Con(T) in Peano Arithmetic. Then he showed that Con(T) is not provable in T.

We say that a metamathematical statement about a theory T is internally provable if its encoding is provable in T. For example, the metamathematical statement “if P is unprovable in T, then T is consistent” is internally provable in T, for any T that satisfies the assumptions of Gödel's second incompleteness theorem.

The type theory in this book satisfies the assumptions of Gödel’s second incompleteness theorem, which include, of course, the assumption that T is consistent. Thus there is no hope that we can prove the consistency of our type theory internally. Moreover, by the previous paragraph, we must be prepared that no unprovability statement can be proved internally.

[TODO For consistency of UA, LEM, etc., refer to simplicial set model7. For unprovability of LEM, refer to cubical set model7.]

One property of type theory that we will use is canonicity. We call an expression closed if it does not contain free variables. One example of canonicity is that every closed expression of type N is a numeral, that is, either 0 or S(n) for some numeral n. Another example of canonicity is that every closed expression of type L LI R is either of the form inl_l for some l : L or of the form inr_r for some r : R.

Both examples of canonicity above are clearly related to the inductive definitions of the types involved: they are expressed in terms of the constructors of the respective types. One may ask what canonicity then means for the empty type False, defined in Section 2.12.1 as the inductive type with no constructors at all. The answer is that canonicity for False means that there cannot be a closed expression of type False. But this actually means that our type theory is consistent! Therefore we cannot prove general canonicity internally.
[TODO no canonical forms: \( x : \mathbb{N}, \text{trp}_P^{\text{id}}(0) : \mathbb{N}, \) with \( P : (p : \text{True} \mapsto \mathbb{N}) \) and (problematic) \( \text{trp}_Q^S(0) : \mathbb{N} \) with \( Q : (z : \mathbb{S}^1 \mapsto \mathbb{N}).] \)

[TODO A second important property of our theory is that one can compute canonical forms.]

\section{Equality by definition}

\subsection{Basics}

The concept of definition was introduced in Section 2.2, together with what it means to be \textit{the same by definition}. Being the same by definition (NB appears for the first time on p. 26!) is a relationship between syntactic expressions. In this section we provide more details about this relationship.

There are four basic forms of equality by definition:

1. Resulting from making an explicit definition, e.g., \( 1 \equiv \text{succ}(0) \), after which we have \( 1 \equiv \text{succ}(0) \);
2. Resulting from making an implicit definition, like we do in inductive definitions, e.g., \( n + 0 \equiv n \) and \( n + \text{succ}(m) \equiv \text{succ}(n + m) \), after which we have \( n + 0 \equiv n \) and \( n + \text{succ}(m) \equiv \text{succ}(n + m) \);
3. Simplifying the application of an explicitly defined function to an argument, e.g., \((x \mapsto e_x)(a) \equiv e_a\);
4. Simplifying \((x \mapsto e_x) \) to \( f \) when \( e_x \) is the application of the function \( f \) to the variable \( x \), e.g., \((x \mapsto S(x)) \equiv S\).

Equality by definition is the \textit{congruence closure} of these four basic forms, that is, the smallest reflexive, symmetric, transitive and congruent relation that contains all instances of the four basic forms. Here a congruent relation is a relation that is closed under all syntactic operations of type theory. One such operation is substitution, so that we get from the examples above that, e.g., \( 1 + 0 \equiv 1 \) and \( n + \text{succ}(\text{succ}(m)) \equiv \text{succ}(n + \text{succ}(m)) \). Another important operation is application. For example, we can apply \text{succ} to each of the sides of \( n + \text{succ}(m) \equiv \text{succ}(n + \text{succ}(m)) \) and get \( \text{succ}(n + \text{succ}(m)) \equiv \text{succ}(\text{succ}(n + m)) \), and also \( n + \text{succ}(\text{succ}(m)) \equiv \text{succ}(\text{succ}(n + m)) \) by transitivity.

Let’s elaborate \( \text{id} \circ f \equiv f \) claimed on page 12. The definitions used on the left hand side are \( \text{id} \equiv (y \mapsto y) \) and \( g \circ f \equiv (x \mapsto g(f(x))) \). In the latter definition we substitute \( \text{id} \) for \( g \) and get \( \text{id} \circ f \equiv (x \mapsto \text{id}(f(x))) \).

Unfolding \( \text{id} \) we get \( (x \mapsto \text{id}(f(x))) \equiv (x \mapsto (y \mapsto y)(f(x))) \). Applying (3) we can substitute \( f(x) \) for \((y \mapsto y)(f(x))) \) and get \( (x \mapsto (y \mapsto y)(f(x))) \equiv (x \mapsto f(x)) \). By (4) the right hand side is equal to \( f \) by definition. Indeed \( \text{id} \circ f \equiv f \) by transitivity.

Equality by definition is also relevant for typing. For example, let \( A : \mathcal{U} \) and \( P : A \rightarrow \mathcal{U} \). If \( B \equiv A \), then \( (B \rightarrow \mathcal{U}) \equiv (A \rightarrow \mathcal{U}) \) by congruence, and also \( P : B \rightarrow \mathcal{U} \), and even \( \prod_{x : B} P(x) \equiv \prod_{x : A} P(x) \).

\subsection{Deciding equality by definition (not updated yet)}

By a \textit{decision procedure} we mean a terminating algorithmic procedure that answers a yes/no question. Although it is possible to enumerate

\footnote{The notation \( \equiv \) tells the reader that we make a definition (or reminds the reader that this definition has been made).}
all true equalities by definition, this does not give a test that answers whether or not a given instance $e \equiv e'$ holds. In particular when $e \equiv e'$ does not hold, such an enumeration will not terminate. A test of equality by definition is important for type checking, as the examples in the last paragraph of the previous section show.

A better approach to a test of equality by definition is the following. First direct the four basic forms of equality by definition from left to right as they are given. For the first two forms this can be viewed as unfolding definitions, and for the last two forms as simplifying function application and (unnecessary) abstraction, respectively. This defines a basic reduction relation, and we write $e \rightarrow e'$ if $e'$ can be obtained by a basic reduction of a subexpression in $e$. The reflexive transitive closure of $\rightarrow$ is denoted by $\rightarrow^*$. The symmetric closure of $\rightarrow^*$ coincides with $\equiv$.

We mention a few important properties of the relations $\rightarrow, \rightarrow^*$ and $\equiv$. The first is called the Church–Rosser property, and states that, if $e \equiv e'$, then there is an expression $c$ such that $e \rightarrow^* c$ and $e' \rightarrow^* c$. The second is called type safety and states that, if $e : T$ and $e \rightarrow e'$, then also $e' : T$. The third is called termination and states that for well-typed expressions $e$ there is no infinite reduction sequence starting with $e$. The proofs of Church–Rosser and type safety are long and tedious, but pose no essential difficulties. For a non-trivial type theory such as in this book the last property, termination, is extremely difficult and has not been carried out in full detail. The closest come results on the Coq (TODO: find good reference).

Testing whether or not two given well-typed terms $e$ and $e'$ are equal by definition can now be done by reducing them with $\rightarrow$ until one reaches irreducible expressions $n$ and $n'$ such that $e \rightarrow^* n$ and $e' \rightarrow^* n'$, and then comparing $n$ and $n'$. Now we have: $e \equiv e'$ iff $n \equiv n'$ iff (by Church–Rosser) there exists a $c$ such that $n \rightarrow^* c$ and $n' \rightarrow^* c$. Since $n$ and $n'$ are irreducible the latter is equivalent to $n$ and $n'$ being identical syntactic expressions.

### B.2 The Limited Principle of Omniscience

**Remark B.2.1.** Recall the Limited Principle of Omniscience (LPO), Principle 3.6.21: for any function $P : \mathbb{N} \rightarrow 2$, either there is a smallest number $n_0 : \mathbb{N}$ such that $P(n_0) = 1$, or $P$ is a constant function with value 0. We will show that LPO is not provable in our theory.

The argument is based on the halting problem: given a Turing machine $M$ and an input $n$, determine whether $M$ halts on $n$. It is known that the halting problem cannot be solved by an algorithm that can be implemented on a Turing machine.\(^{11}\)

We use a few more facts from computability theory. First, Turing machines can be enumerated. We denote the $n^{th}$ Turing machine $M_n$, so we can list the Turing machines in order: $M_0, M_1, \ldots$. Secondly, there exists a function $T(e, n, k)$ such that $T(e, n, k) = 1$ if $M_k$ halts on input $n$ in at most $k$ steps, and $T(e, n, k) = 0$ otherwise. This function $T$ can be implemented in our theory.

Towards a contradiction, assume we have a closed proof $t$ of LPO in our theory. We assume as well that $t$ does not depend on any axiom.\(^{12}\) It is clear that $k \mapsto T(e, n, k)$ is a constant function with value 0 if and only for some $k$.

\(^{9}\) TODO: think about the last, $\eta$.

\(^{10}\) The Coq Development Team. The Coq Proof Assistant. Available at https://coq.inria.fr/.

\(^{11}\) It’s commonly accepted that every algorithm can be thus implemented.

\(^{12}\) It is possible to weaken the notion of canonicity so that the argument still works even if the proof $t$ uses the Univalence Axiom. Of course, the argument must fail if we allow $t$ to use LEM!
if \( M_n \) does not halt on input \( n \). Now consider \( t(k \mapsto T(e, n, k)) \), which is an element of a type of the form \( LLI R \).

We now explain how to solve the halting problem. Let \( e \) and \( n \) be arbitrary numerals. Then \( t(k \mapsto T(e, n, k)) \) is a closed element of \( LLI R \). Hence we can compute its canonical form. If \( t(k \mapsto T(e, n, k)) \equiv \text{inr} \), for some \( r : R \), then \( k \mapsto T(e, n, k) \) is a constant function with value 0, and \( M_e \) does not halt on input \( n \). If \( t(k \mapsto T(e, n, k)) \equiv \text{inl} \), for some \( l : L \), then \( M_e \) does halt on input \( n \). Thus we have an algorithm to solve the halting problem for all \( e \) and \( n \). Since this is impossible, we have refuted the assumption that there is a closed proof \( t \) of LPO in our theory. \[ \]

B.3 Topology

In this section we will explain how our intuition about types relates to our intuition about topological spaces.

INSERT AN INTRODUCTORY PARAGRAPH HERE. [Intuitively, the types of type theory can be modeled by topological spaces, and elements as points thereof. However, this is not so easy to achieve, and the first model of homotopy theory theory was in simplicial sets. Topological spaces and simplicial sets are both models of homotopy types. And by a lucky coincidence, it makes sense to say that homotopy type theory is a theory of homotopy types.] Some references include: Hatcher, May, and May and Ponto.\[13\]

Remark B.3.1. Our definitions of injections and surjections are lifted directly from the intuition about sets. However, types need not be sets, and thinking of types as spaces may at this point lead to a slight confusion.

The real line is contractible and the inclusion of the discrete subspace \{0, 1\} is, well, an inclusion (of sets, which is the same thing as an inclusion of spaces). However, \{0, 1\} is not connected, seemingly contradicting the next result.

This apparent contradiction is resolved once one recalls the myopic nature of our setup: the contractibility of the real line means that “all real numbers are identical”, and our “preimage of 3.25” is not a proposition: it contains both 0 and 1. Hence “\{0, 1\} \subseteq \mathbb{R}” would not count as an injection in our sense.

We should actually have been more precise above: we were referring to the homotopy type of the real line, rather than the real line itself.\[14\] We shall later (in the chapters on geometry) make plenty of use of the latter, which is as usual a set with uncountably many elements. \[ \]

B.4 Choice for finite sets (†)

This section is a short overview of how group theory is involved in relating different choice principles for families of finite sets. A paradigmatic case is that if we have choice for all families of 2-element sets, then we have choice for all families of 4-element sets.\[16\]

The axiom of choice is a principle that we may add to our type theory (it holds in the standard model), but there are many models where it doesn’t hold.
PRINCIPLE B.4.1 (The Axiom of Choice). For every set $X$ and every family of non-empty sets $P : X \to \text{Set}_{\neq 0}$, there exists an dependent function of type $\prod_{x : X} P(x)$. In other terms, for any set $X$ and any family of sets $P : X \to \text{Set}$, we have

\[
\prod_{x : X} \|P(x)\| \to \|\prod_{x : X} P(x)\|.
\]  

REMARK B.4.2. We have an equivalence between the Pi-type $\prod_{x : X} P(x)$ and the type of sections of the projection map $\text{pr}_1 : \Sigma_{x : X} P(x) \to X$, under which families of non-empty sets correspond to surjections between sets (using that $X$ is a set). Thus, the axiom of choice equivalently says that any surjection between sets admits a section.

Because of this equivalence, we’ll sometimes also call elements of the Pi-type sections.

The following is usually called Diaconescu’s theorem\(^\text{18}\) or the Goodman–Myhill theorem\(^\text{19}\), but it was first observed in a problem in Bishop’s book on constructive analysis\(^\text{20}\).

THEOREM B.4.3. The axiom of choice implies the law of the excluded middle, Principle 2.18.2.

Proof. Let $P$ be a proposition, and consider the quotient map $q : 2 \to 2/\sim$, where $\sim$ is the equivalence relation on $2$ satisfying $(0 \sim 1) = P$. Like any quotient map, $q$ is surjective, so by the axiom of choice, and because our goal is a proposition, it has a section $s : 2/\sim \to 2$. That is, we also have $q \circ s = \text{id}$.

Using decidable equality in $2$, check whether $s([0])$ and $s([1])$ are equal or not.

If they are, then we get the chain of identifications $[0] = q(s([0])) = q(s([1])) = [1]$, so $P$ holds.

If they aren’t, then assuming $P$ leads to a contradiction, meaning $\neg P$ holds.

We’ll now define some restricted variants of the axiom of choice, that however are not always true, and our goal is to see how they relate to each other and to other principles.

DEFINITION B.4.4. Let $\text{AC}$ denote the full axiom of choice, as in Principle B.4.1. If we fix the set $X$, and consider (B.4.1) for arbitrary families $P : X \to \text{Set}$, we call this the $X$-local axiom of choice, denoted $X$-$\text{AC}$.

If we restrict $P$ to take values in $n$-element sets, for some $n : \mathbb{N}$, we denote the resulting principle $\text{AC}(n)$. (That is, here we consider families $P : X \to \text{B} \Sigma_n$.)

If we both fix $X$ and restrict to families of $n$-element sets, we denote the resulting principle $X$-$\text{AC}(n)$.

EXERCISE B.4.5. Show that $X$-$\text{AC}$ is always true whenever $X$ is a finite set.

LEMMA B.4.6. If $X$-$\text{AC}$ holds for a set $X$, then $\|X \to BG\|_0$ is contractible for any group $G$.

Proof. Suppose we have a map $f : X \to BG$. We need to show that $f$ is merely equal to the constant map. Consider the corresponding family of sets consisting of the underlying sets of the $G$-torsors represented by

\footnotesize

In fancier language, this says that the axiom of choice implies that all cohomology sets $H^1(X, G)$ are trivial.
We might wonder what happens if we consider general \(\infty\)-groups \(G\) in Lemma B.4.6. Then the underlying type of a \(G\)-torsor is no longer a set, but can be any type. Correspondingly, we need an even stronger version of the axiom of choice, where the family \(P\) is allowed to be arbitrary. Let \(AC_\infty\) denote this untruncated axiom of choice, and let \(X-AC_\infty\) denote \(X\) local version, fixing a set \(X\). This is connected to another principle, which is much more constructive, yet still not true in all models.

Principle B.4.7 (Sets Cover). For any type \(A\), there exists a set \(X\) together with a surjection \(X \to A\).

We abbreviate this as SC.

Exercise B.4.8. Prove that the untruncated axiom of choice, \(AC_\infty\), is equivalent to the conjunction of the standard axiom of choice, \(AC\), and the principle that sets cover, SC.

Exercise B.4.9. Prove that we cannot relax the requirement that \(X\) is a set in the axiom of choice. Specifically, prove that \(S^1\-AC(2)\) is false.

We now come to the analogue of Lemma B.4.6 for arbitrary \(\infty\)-groups.

Exercise B.4.10. Prove that if the untruncated \(X\)-local axiom of choice, \(X-AC_\infty\), holds for a set \(X\), then \(\|X \to BG\|_0\) is contractible for all \(\infty\)-groups \(G\).

We now discuss two partial converses to Lemma B.4.6, both due to Blass.

Theorem B.4.11 (Blass). Let \(X\) be a set such that \(\|X \to BG\|_0\) is contractible for all groups \(G\). Then every family of non-empty sets over \(X\), \(P : X \to \text{Set}\), that factors through a connected component of \(\text{Set}\), merely admits a section.

Proof. We suppose \(P : X \to \text{Set}\) is such that all the sets \(P(x)\) have the same size, i.e., the function \(P\) factors through \(\text{BAut}(S)\) for some non-empty set \(S\). This in turn means that we have a function \(h : X \to BG\), where \(G \equiv \text{Aut}(S)\), with \(P = \text{pr}_1 \circ h\), where \(\text{pr}_1 : \text{BAut}(S) = \sum_{A : \text{Set}} \|S \simeq A\| \to \text{Set}\) is the projection.

By assumption, \(h\) is merely equal to the constant family. But since we are proving a proposition, we may assume that \(h\) is constant, so \(P\) is the constant family at \(S\). And this has a section since \(S\) is non-empty.

Obviously, the same argument works if we consider all \(\infty\)-groups \(G\) and families of types that are all equivalent. For the second partial converse, we look at decidable sets.

Theorem B.4.12 (Blass). Let \(X\) be a decidable set such that \(\|X \to BG\|_0\) is contractible for all groups \(G\). Then every family of non-empty decidable sets over \(X\) merely admits a section.

Proof. Equivalently, consider a surjection \(p : Y \to X\), where \(X\) and \(Y\) are decidable sets, and let \(C\) be the higher inductive type with constructors \(c : C\), \(f : X \to C\), and \(k : \prod_{y : Y} (c = f(p(y)))\). Using the same kind of...
argument as in Lemma 4.16.7 and Theorem 6.2.9, we can show, using decidability of equality in X and Y, that the identity type \( c \equiv \text{f}(x) \) is equivalent to a type of reduced words over \( Y \sqcup Y \). In particular, \( C \) is a groupoid, and it’s easy to check that it’s connected. Hence we can form the group \( G \equiv \Omega(C, c) \).

By assumption, the map \( f \) is merely equal to the constant map, so since we’re proving a proposition, we may assume we have a family of elements \( h(x) : c = f(x) \), for \( x : X \). Taking for each \( x \) the last \( y \) in the corresponding reduced word, we get a family of elements \( s(x) : Y \) such that \( p(s(x)) = x \), but this is precisely the section we wanted. \( \square \)

It seems to be an open problem, whether we can do without the decidability assumption, i.e., whether the converse of Lemma B.4.6 holds generally.

Now we turn as promised to the connections between the various local choice principles \( X\)-AC\( (n) \). The simplest example is the following.

**Theorem B.4.13.** Let \( X \) be any set. Then \( X\)-AC\( (4) \) follows from \( X\)-AC\( (2) \) and \( X\)-AC\( (3) \).

**Proof.** Let \( P : X \to B\Sigma_4 \) be a family of 4-element sets indexed by a set \( X \). Consider the map \( Bf : B\Sigma_4 \to B\Sigma_3 \) that maps a 4-element set to the 3-element set of its \( 2 + 2 \) partitions. Choose a section of \( Bf \circ P \) by \( X\)-AC\( (3) \). Now use \( X\)-AC\( (2) \) twice to choose for each chosen partition first one of the \( 2 \)-element parts, and secondly one of the 2 elements in each chosen part. \( \square \)

We now look a bit more closely at what happened in this proof, so as to better understand the general theorem. The key idea is the concept of “reduction of the structure group”.

[TODO, Elaborate: For a family of \( n \)-element sets over a base type \( X \), \( P : X \to B\Sigma_n \), there is a section if and only if there is a “ to a subgroup of \( \Sigma_n \), whose action on the standard \( n \)-element set, \( n \), has a fixed point.]

Now we return to the local case, and we give the general sufficient condition that ensures that \( X\)-AC\( (n) \) follows from \( X\)-AC\( (z) \) for each \( z : Z \), where \( Z \) is a finite subset of \( \mathbb{N} \).

**Definition B.4.14.** The condition \( L(Z, n) \) is that for every finite subgroup \( G \) of \( \Sigma_n \) that acts on \( n \) without fixed points, there exists finitely many proper, finite subgroups \( K_1, \ldots, K_r \) of \( G \) such that the sum of the indices,

\[
|G : H_1| + \cdots + |G : H_r|,
\]

lies in \( Z \). \( \downarrow \)

We now turn to the global case, where we can change the base set. Here the basic case is Tarski’s result alluded to above, which shows that we don’t need choice for 3-element sets, in contrast to the local case, Theorem B.4.13.

**Theorem B.4.15.** AC\( (2) \) implies AC\( (4) \).

**Proof.** Let \( P : X \to B\Sigma_4 \) be a family of 4-element sets indexed by a set \( X \). Consider the new set \( Y \) consisting of all 2-element subsets of \( P(x) \), as \( x \) runs over \( X \),

\[
Y \equiv \sum_{x : X} |P(x)|^2.
\]
The set $Y$ carries a canonical family of 2-element sets, so we may choose an element of each. In other words, we have chosen an element of each of the 6 different 2-element subsets of each of the 4-element sets $P(x)$.

For every $a : P(x)$, let $q_x(a)$ be the number of 2-element subsets $\{a, b\}$ of $P(x)$ with $b \neq a$ for which $a$ is the chosen element.

Define the sets $B(x) \coloneqq \{ a : P(x) \mid q_x(a) \text{ is a minimum of } q_x \}$, and remember that they are subsets of $P(x)$. This determines a decomposition of $X$ into three parts $X = X_1 + X_2 + X_3$, where

$$X_i \coloneqq \sum_{x \in X} (B(x) \text{ has cardinality } i), \quad i = 1, 2, 3.$$ 

Note that $B(x)$ can’t be all of $P(x)$, since that would mean that $q_x$ is constant, and that is impossible, since the sum of $q_x$ over the 4-element $P(x)$ is 6.

Over $X_1$, we get a section of $P$ by picking the unique element in $B(x)$.

Over $X_2$, we get a section of $P$ by picking the already chosen element of the 2-element set $B(x)$.

Over $X_3$, we get a section of $P$ by picking the already chosen element of each of the 2-element sets, we can express equality, so we can form the $(n - 1)$-element complement $P(x) \setminus \{y\}$.

By induction hypothesis, we get a section of $Q$, which we can express as a family of functions $f : \prod_{x \in X} (P(x) \to P(x))$ where $f_x(y) \neq y$ for all $x, y$. Since $P(x)$ is an $n$-element set, we can decide whether $f_x$ is a permutation or not, and if so, whether it is a cyclic permutation. We have thus obtained a partition $X = X_1 + X_2 + X_3$, where

$$X_1 \coloneqq \{ x : X \mid f_x \text{ is not a permutation } \},$$

$$X_2 \coloneqq \{ x : X \mid f_x \text{ is a non-cyclic permutation } \},$$

$$X_3 \coloneqq \{ x : X \mid f_x \text{ is a cyclic permutation } \}.$$ 

We get a section of $P$ over $X_1$ by induction hypothesis by considering the family of the images of $f_x$.

We get a section of $P$ over $X_2$ by first choosing a cycle of $f_x$ (there are fewer then $n$ cycles because there are no 1-cycles), and then choosing an element of the chosen cycle.

We get a section of $P$ over $X_3$ by the assumption applied to the map $X_3 \to \BC_n$ induced by equipping each $P(x)$ with the cyclic order determined by the cyclic permutation $f_x$. 

\footnote{Blass, "Cohomology detects failures of the axiom of choice".}
[TODO: State the general positive result due to Mostowski, maybe as an exercise and give references to the negative results, due to Gauntt (unpublished).]

0 · the natural number zero, Peano’s rules, Item (P2), 13
1 · the natural number 1, 14
2 · the natural number 2, 14
3 · the natural number 3, 14
Ω · homomorphism constructor, Definition 4.4.2, 107
apf · application of f to a path, Definition 2.6.1, 19
apdf · application of a dependent function to a path, Definition 2.7.6, 21
AutA(a) · automorphism group of the element a in the type A, Definition 4.2.14, 99
Cay(G; S) · Cayley graph of a group G with respect to S, 182
coker f · cokernel of a homomorphism f, 155
Cyc · the type of cycles, Definition 3.6.3, 76
Cyc0 · the type of infinite cycles, Definition 3.8.1, 84
EpiG · type of epimorphisms from the group G, 152
FinSet · the groupoid of finite sets, 55
FinSetn · the groupoid of sets of cardinality n, 55
F S · free group on a decidable set of generators, 178
id · identity function, 12
im(f) · the (propositional) image of f, 42
imn(f) · the n-image of f, 89
InfCyc · the type of infinite cycles, Definition 3.5.3, 73
inn · homomorphism from G to its inner automorphisms, Definition 4.4.27, 112
MonoG · G-set of monomorphisms into G, 160
MonoG · type of monomorphisms into the group G, 152
ℕ · the type of natural numbers, Peano’s rules, Item (P1), 13
ℕ− · the type of negated natural numbers, Example 2.12.9, 31
ns · naturality square, Definition 2.6.5, 20
po p · convert path over path, Definition 2.7.3, 20
ptX · base point of a pointed type X, 46
refl a · reflexivity, identity type, Item (E2), 15
s · successor function on Z, 63
sgn · sign homomorphism, Definition 4.5.6, 114
SubG · type of subgroups of G, 153
\{ t : T | P(t) \} · set comprehension, 45
succ · the successor function on ℕ, Peano’s rules, Item (P3), 13
tot(f) · totalization of f, 25
Tot(Y) · the total type \( \sum_{x:X} Y(x) \), 22
trpf · transport function, Definition 2.5.4, 18
\text{twist} · interchange the elements of Bool, Exercise 2.13.3, 32
uaXY · postulated element of the univalence axiom, 31
\( \mathbb{P}_b \) · the type family \( b \mapsto (b_0 \Rightarrow b) \), 67
\mathcal{U} · universe, 13
\mathcal{U}^1 · pointed, connected groupoids, Definition 4.2.6, 97
\mathcal{U}_* · universe of pointed types, Definition 2.21.1, 46
wdg · winding number function, 71
Z · the set of integers, Definition 3.2.1, 63
Z · group of integers, Example 4.2.17, 99
Z · the set of integers, Definition 3.2.1, 63
Z · group of integers, Example 4.2.17, 99
